If $jobz = 'V'$, *nz* = *m* unless the user supplies insufficient space and $p?\text{syevx}$ is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* (i.e. *descz(n_)*) and sufficient workspace to compute them. (See *lwork*). $p?\text{syevx}$ is always able to detect insufficient space without computation unless *range.eq.'V'*.

w

(global). REAL for pssyevx

DOUBLE PRECISION for pdsyevx .

Array, DIMENSION (*n*). The first *m* elements contain the selected eigenvalues in ascending order.

z (local). REAL for pssyevx
 DOUBLE PRECISION for pdsyevx.
 Array, global dimension (n, n), local dimension ($l1d_z, LOCC(jz+n-1)$).
 If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
 If $jobz = 'N'$, then z is not referenced.

work(1) On exit, returns workspace adequate workspace to allow optimal performance.

iwork(1) On return, *iwork(1)* contains the amount of integer workspace required.

ifail (global) INTEGER.
 Array, DIMENSION (n).
 If $jobz = 'V'$, then on normal exit, the first m elements of *ifail* are zero.
 If $(\text{mod}(info, 2) .ne. 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.
 If $jobz = 'N'$, then *ifail* is not referenced.

iclustr (global) INTEGER. Array, DIMENSION ($2 * \text{NPROW} * \text{NPCOL}$)
 This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*($2*i-1$) to *iclustr*($2*i$), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr()* is a zero terminated array. (*iclustr*($2*k$) .ne. 0. and. *iclustr*($2*k+1$) .eq. 0) if and only if k is the number of clusters.
iclustr is not referenced if $jobz = 'N'$.

gap (global)
 REAL for pssyevx
 DOUBLE PRECISION for pdsyevx.
 Array, DIMENSION ($\text{NPROW} * \text{NPCOL}$)
 This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C * n) / gap(i)$ where C is a small constant.

info (global) INTEGER.
 If *info* = 0, the execution is successful.
 If *info* < 0:
 If the i -th argument is an array and the j -entry had an illegal value, then *info* = $-(i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then *info* = $-i$.
 If *info* > 0: if $(\text{mod}(info, 2) .ne. 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*= $2.0 * p?lamch('U')$.
 If $(\text{mod}(info/2, 2) .ne. 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(info/4,2).ne.0), then space limit prevented p?syevxf from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.
 If (mod(info/8,2).ne.0), then p?stebz failed to compute eigenvalues.
 Ensure abstol=2.0*p?lamch('U').

p?heev

Computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix.

Syntax

```
call pccheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork, lrwork, info)
call pzheev(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork, rwork, lrwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?heev routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* by calling the recommended sequence of ScaLAPACK routines. The routine assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global). CHARACTER*1. Must be 'N' or 'V'.
 Specifies if it is necessary to compute the eigenvectors:
 If *jobz* = 'N', then only eigenvalues are computed.
 If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global). CHARACTER*1. Must be 'U' or 'L'.
 Specifies whether the upper or lower triangular part of the Hermitian matrix *A* is stored:
 If *uplo* = 'U', *a* stores the upper triangular part of *A*.
 If *uplo* = 'L', *a* stores the lower triangular part of *A*.

n (global) INTEGER. The number of rows and columns of the matrix *A* (*n* \geq 0).

a (local).
 COMPLEX for pccheev
 DOUBLE COMPLEX for pzheev.
 Block cyclic array of global dimension (*n*, *n*) and local dimension (*lld_a*, *LOCc(ja+n-1)*). On entry, the Hermitian matrix *A*.
 If *uplo* = 'U', only the upper triangular part of *A* is used to define the elements of the Hermitian matrix.
 If *uplo* = 'L', only the lower triangular part of *A* is used to define the elements of the Hermitian matrix.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>descA</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _). The array descriptor for the distributed matrix <i>A</i> . If <i>descA(ctxt_)</i> is incorrect, p?heev cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descZ</i>	(global and local) INTEGER array, dimension (<i>dlen</i> _). The array descriptor for the distributed matrix <i>Z</i> . <i>descZ(ctxt_)</i> must equal <i>descA(ctxt_)</i> .
<i>work</i>	(local). COMPLEX for pcheev DOUBLE COMPLEX for pzheev. Array, DIMENSION <i>lwork</i> .
<i>lwork</i>	(local). INTEGER. The dimension of the array <i>work</i> . If only eigenvalues are requested (<i>jobz</i> = 'N'): $lwork \geq \max(nb * (np0 + 1), 3) + 3*n$ If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required: $lwork \geq (np0 + nq0 + nb) * nb + 3*n + n^2$ with <i>nb</i> = <i>descA(mb_)</i> = <i>descA(nb_)</i> = <i>nb</i> = <i>descZ(mb_)</i> = <i>descZ(nb_)</i> <i>np0</i> = numroc(<i>nn</i> , <i>nb</i> , 0, 0, <i>NPROW</i>). <i>nq0</i> = numroc($\max(n, nb, 2)$, <i>nb</i> , 0, 0, <i>NPCOL</i>). If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.
<i>rwork</i>	(local). REAL for pcheev DOUBLE PRECISION for pzheev. Workspace array, DIMENSION <i>lrwork</i> .
<i>lrwork</i>	(local) INTEGER. The dimension of the array <i>rwork</i> . See below for definitions of variables used to define <i>lrwork</i> . If no eigenvectors are requested (<i>jobz</i> = 'N'), then <i>lrwork</i> $\geq 2*n$. If eigenvectors are requested (<i>jobz</i> = 'V'), then <i>lrwork</i> $\geq 2*n + 2*n - 2$. If <i>lrwork</i> = -1, then <i>lrwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum size required for the <i>rwork</i> array. The required workspace is returned as the first element of <i>rwork</i> , and no error message is issued by pxerbla.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). REAL for pcheev DOUBLE PRECISION for pzheev. Array, DIMENSION <i>n</i> . The first <i>m</i> elements contain the selected eigenvalues in ascending order.

z (local).
 COMPLEX for pcheev
 DOUBLE COMPLEX for pzheev.
 Array, global dimension (n, n), local dimension ($l1d_z, LOCC(jz+n-1)$).
 If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.
 If $jobz = 'N'$, then z is not referenced.

work(1) On exit, returns adequate workspace to allow optimal performance.
 If $jobz = 'N'$, then $work(1) =$ minimal workspace only for eigenvalues.
 If $jobz = 'V'$, then $work(1) =$ minimal workspace required to generate all the eigenvectors.

rwork(1) (local)
 COMPLEX for pcheev
 DOUBLE COMPLEX for pzheev.
 On output, $rwork(1)$ returns workspace required to guarantee completion.

info (global) INTEGER.
 If $info = 0$, the execution is successful.
 If $info < 0$:
 If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$. If the i -th argument is a scalar and had an illegal value, then $info = -i$.
 If $info > 0$:
 If $info = 1$ through n , the i -th eigenvalue did not converge in [?steqr2](#) after a total of $30*n$ iterations.
 If $info = n+1$, then p?heev detected heterogeneity, and the accuracy of the results cannot be guaranteed.

p?heevd

Computes all eigenvalues and eigenvectors of a complex Hermitian matrix by using a divide and conquer algorithm.

Syntax

```
call pcheevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
rwork, lrwork, iwork, liwork, info)

call pzheevd(jobz, uplo, n, a, ia, ja, desca, w, z, iz, jz, descz, work, lwork,
rwork, lrwork, iwork, liwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?heevd routine computes all eigenvalues and eigenvectors of a complex Hermitian matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global). CHARACTER*1. Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) INTEGER. The number of rows and columns of the matrix <i>A</i> (<i>n</i> \geq 0).
<i>a</i>	(local). COMPLEX for pcheevd DOUBLE COMPLEX for pzheevd. Block cyclic array of global dimension (<i>n</i> , <i>n</i>) and local dimension (<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>descA</i>	(global and local) INTEGER array, dimension (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>descA(ctxt_)</i> is incorrect, p?heevd cannot guarantee correct error reporting.
<i>iz</i> , <i>iz</i>	(global) INTEGER. The row and column indices in the global array <i>z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descZ</i>	(global and local) INTEGER array, dimension <i>dlen</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descZ(ctxt_)</i> must equal <i>descA(ctxt_)</i> .
<i>work</i>	(local). COMPLEX for pcheevd DOUBLE COMPLEX for pzheevd. Array, DIMENSION <i>lwork</i> .
<i>lwork</i>	(local). INTEGER. The dimension of the array <i>work</i> . If eigenvalues are requested: <i>lwork</i> = <i>n</i> + (<i>nb0</i> + <i>mq0</i> + <i>nb</i>) * <i>nb</i> with <i>np0</i> = numroc(max(<i>n</i> , <i>nb</i> , 2), <i>nb</i> , 0, 0, NPROW) <i>mq0</i> = numroc(max(<i>n</i> , <i>nb</i> , 2), <i>nb</i> , 0, 0, NPCOL) If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by pxerbla.
<i>rwork</i>	(local). REAL for pcheevd DOUBLE PRECISION for pzheevd. Workspace array, DIMENSION <i>lrwork</i> .
<i>lrwork</i>	(local) INTEGER. The dimension of the array <i>rwork</i> . <i>lrwork</i> \geq 1 + 9*n + 3*np* <i>nq</i> ,

```

with np = numroc( n, nb, myrow, iarow, NPROW)
nq = numroc( n, nb, mycol, iacol, NPCOL)
iwork (local) INTEGER. Workspace array, dimension lwork.
liwork (local) INTEGER, dimension of iwork.
liwork = 7*n + 8*ncol + 2.
```

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). REAL for pcheevd DOUBLE PRECISION for pzheevd. Array, DIMENSION <i>n</i> . If <i>info</i> = 0, <i>w</i> contains the eigenvalues in the ascending order.
<i>z</i>	(local). COMPLEX for pcheevd DOUBLE COMPLEX for pzheevd. Array, global dimension (<i>n</i> , <i>n</i>), local dimension (<i>lld_z</i> , LOCc(<i>jz+n-1</i>)). The <i>z</i> parameter contains the orthonormal eigenvectors of the matrix <i>A</i> .
<i>work(1)</i>	On exit, returns adequate workspace to allow optimal performance.
<i>rwork(1)</i>	(local) COMPLEX for pcheevd DOUBLE COMPLEX for pzheevd. On output, <i>rwork(1)</i> returns workspace required to guarantee completion.
<i>iwork(1)</i>	(local). On return, <i>iwork(1)</i> contains the amount of integer workspace required.
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>). If the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> > 0: If <i>info</i> = 1 through <i>n</i> , the <i>i</i> -th eigenvalue did not converge.

p?heevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

```

call pcheevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz,
w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr,
gap, info)

call pzheevx(jobz, range, uplo, n, a, ia, ja, desca, vl, vu, il, iu, abstol, m, nz,
w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork, iwork, liwork, ifail, iclustr,
gap, info)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?heevx` routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK routines. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

`np` = the number of rows local to a given process.

`nq` = the number of columns local to a given process.

<code>jobz</code>	(global). CHARACTER*1. Must be ' <code>N</code> ' or ' <code>V</code> '. Specifies if it is necessary to compute the eigenvectors: If <code>jobz</code> = ' <code>N</code> ', then only eigenvalues are computed. If <code>jobz</code> = ' <code>V</code> ', then eigenvalues and eigenvectors are computed.
<code>range</code>	(global). CHARACTER*1. Must be ' <code>A</code> ', ' <code>V</code> ', or ' <code>I</code> '. If <code>range</code> = ' <code>A</code> ', all eigenvalues will be found. If <code>range</code> = ' <code>V</code> ', all eigenvalues in the half-open interval $[vl, vu]$ will be found. If <code>range</code> = ' <code>I</code> ', the eigenvalues with indices <code>il</code> through <code>iu</code> will be found.
<code>uplo</code>	(global). CHARACTER*1. Must be ' <code>U</code> ' or ' <code>L</code> '. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: If <code>uplo</code> = ' <code>U</code> ', A stores the upper triangular part of A . If <code>uplo</code> = ' <code>L</code> ', A stores the lower triangular part of A .
<code>n</code>	(global) INTEGER. The number of rows and columns of the matrix A ($n \geq 0$).
<code>a</code>	(local). COMPLEX for <code>pccheevx</code> DOUBLE COMPLEX for <code>pzcheevx</code> . Block cyclic array of global dimension (n, n) and local dimension $(lld_a, LOC c(ja+n-1))$. On entry, the Hermitian matrix A . If <code>uplo</code> = ' <code>U</code> ', only the upper triangular part of A is used to define the elements of the Hermitian matrix. If <code>uplo</code> = ' <code>L</code> ', only the lower triangular part of A is used to define the elements of the Hermitian matrix.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.
<code>desca</code>	(global and local) INTEGER array, dimension $(dlen_)$. The array descriptor for the distributed matrix A . If <code>desca(ctxt_)</code> is incorrect, <code>p?heevx</code> cannot guarantee correct error reporting.
<code>vl, vu</code>	(global) REAL for <code>pccheevx</code> DOUBLE PRECISION for <code>pzcheevx</code> . If <code>range</code> = ' <code>V</code> ', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <code>range</code> = ' <code>A</code> ' or ' <code>I</code> '.
<code>il, iu</code>	(global) INTEGER. If <code>range</code> = ' <code>I</code> ', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1$; $\min(il, n) \leq iu \leq n$. Not referenced if <code>range</code> = ' <code>A</code> ' or ' <code>V</code> '.

abstol (global).
REAL for `pcheevx`
DOUBLE PRECISION for `pzheevx`.
If $jobz = 'V'$, setting *abstol* to `p?lamch(context, 'U')` yields the most orthogonal eigenvectors.
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + \text{eps} * \max(|a|, |b|)$, where *eps* is the machine precision. If *abstol* is less than or equal to zero, then *eps***norm(T)* will be used in its place, where *norm(T)* is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.
Eigenvalues are computed most accurately when *abstol* is set to twice the underflow threshold $2 * p?lamch('S')$, not zero. If this routine returns with $((\text{mod}(info, 2) .ne. 0) .or. (\text{mod}(info/8, 2) .ne. 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to $2 * p?lamch('S')$.

orfac (global). **REAL** for `pcheevx`
DOUBLE PRECISION for `pzheevx`.
Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of $1.0e-3$ is used if *orfac* is negative.
orfac should be identical on all processes.

iz, jz (global) **INTEGER**. The row and column indices in the global array *z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz (global and local) **INTEGER array, dimension (dlen_)**. The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work (local).
COMPLEX for `pcheevx`
DOUBLE COMPLEX for `pzheevx`.
Array, DIMENSION lwork.

lwork (local). **INTEGER**. The dimension of the array *work*.
If only eigenvalues are requested:
 $lwork \geq n + \max(nb * (np0 + 1), 3)$
If eigenvectors are requested:
 $lwork \geq n + (np0 + mq0 + nb) * nb$
with $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$.
 $lwork \geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{ceil}(neig, \text{NPROW} * \text{NPCOL}) * nn$
For optimal performance, greater workspace is needed, that is
 $lwork \geq \max(lwork, nhetrld_lwork)$
where *lwork* is as defined above, and $nhetrld_lwork = n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$
 $ictxt = desca(ctxt_)$
 $anb = \text{pjlaenv}(ictxt, 3, 'pchetrd', 'L', 0, 0, 0, 0)$
 $sqnpes = \sqrt{dble(\text{NPROW} * \text{NPCOL}))}$
 $nps = \max(\text{numroc}(n, 1, 0, 0, sqnpes), 2 * anb)$

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxebla.

$rwork$

(local)

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Workspace array, DIMENSION $lrwork$.

$lrwork$

(local) INTEGER. The dimension of the array $work$.

See below for definitions of variables used to define $lwork$.

If no eigenvectors are requested ($jobz = 'N'$), then $lrwork \geq 5*nn + 4*n$.

If eigenvectors are requested ($jobz = 'V'$), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lrwork \geq 4*n + \max(5*nn, np0*mq0+2*nb*nb) + \text{ceil}(neig, \text{NPROW}*\text{NPCOL}) * nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and $orfac$ is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to $lwork$:

$(clustersize-1)*n$,

where $clustersize$ is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+clustersize-1) | w(j+1) \leq w(j) + orfac*2*norm(A)\}.$$

Variable definitions:

$neig$ = number of eigenvectors requested;

$nb = descra(mb_)$ = $descra(nb_)$ = $descz(mb_)$ = $descz(nb_)$;

$nn = \max(n, NB, 2)$;

$descra(rsrc_)$ = $descra(nb_)$ = $descz(rsrc_)$ = $descz(csdc_)$ = 0;

$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW})$;

$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, \text{NPCOL})$;

$\text{ceil}(x, y)$ is a ScaLAPACK function returning $\text{ceiling}(x/y)$

When $lwork$ is too small:

If $lwork$ is too small to guarantee orthogonality, p?heevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If $lwork$ is too small to compute all the eigenvectors requested, no computation is performed and $info = -23$ is returned. Note that when $range='V'$, p?heevx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when $range='V'$ and as long as $lwork$ is large enough to allow p?heevx to compute the eigenvalues, p?heevx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If $clustersize \geq n/\sqrt{NPROW*\text{NPCOL}}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) p?stein will perform no better than ?stein on 1 processor.

For $clustersize = n/\sqrt{NPROW*\text{NPCOL}}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $\text{clustersize} > n/\sqrt{(\text{NPROW} \cdot \text{NPCOL})}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $\text{lwork} = -1$, then lwork is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

$iwork$

(local) INTEGER. Workspace array.

$liwork$

(local) INTEGER, dimension of $iwork$.

$liwork \geq 6 * nnp$

Where: $nnp = \max(n, \text{NPROW} \cdot \text{NPCOL} + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit, the lower triangle (if $uplo = 'L'$), or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

m

(global) INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.

nz

(global) INTEGER. Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and p?heevx is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z (m.le.descz(n_)) and sufficient workspace to compute them. (See $lwork$). p?heevx is always able to detect insufficient space without computation unless range.eq.'V'.

w

(global).

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array, DIMENSION (n). The first m elements contain the selected eigenvalues in ascending order.

z

(local).

COMPLEX for pcheevx

DOUBLE COMPLEX for pzheevx.

Array, global dimension (n, n), local dimension ($lld_z, LOCC(jz+n-1)$).

If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

$work(1)$

On exit, returns adequate workspace to allow optimal performance.

$rwork$

(local).

REAL for pcheevx

DOUBLE PRECISION for pzheevx.

Array, DIMENSION (*lwork*). On return, *rwork*(1) contains the optimal amount of workspace required for efficient execution.

If *jobz*='N' *rwork*(1) = optimal amount of workspace required to compute eigenvalues efficiently.

If *jobz*='V' *rwork*(1) = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*='V', it is assumed that all eigenvectors may be required.

iwork(1)

(local)

On return, *iwork*(1) contains the amount of integer workspace required.

ifail

(global) INTEGER.

Array, DIMENSION (*n*).

If *jobz* ='V', then on normal exit, the first *m* elements of *ifail* are zero.

If (mod(*info*,2).ne.0) on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

iclustr

(global) INTEGER.

Array, DIMENSION (2*NPROW*NPCOL).

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr*() is a zero terminated array. (*iclustr*(2*k).ne.0. and. *iclustr*(2*k +1).eq.0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

REAL for *pcheevx*

DOUBLE PRECISION for *pzheevx*.

Array, DIMENSION (NPROW*NPCOL)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as $(C*n)/gap(i)$ where *C* is a small constant.

info

(global) INTEGER.

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

If (mod(*info*,2).ne.0), then one or more eigenvectors failed to converge.

Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U')

If (mod(*info*/2,2).ne.0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4,2).ne.0), then space limit prevented *p?syevx* from computing all of the eigenvectors between *vl* and *. The number of eigenvectors computed is returned in *nz*.*

If (mod(*info*/8,2).ne.0), then p?stebz failed to compute eigenvalues.
Ensure abstol=2.0*p?lamch('U').

p?gesvd

Computes the singular value decomposition of a general matrix, optionally computing the left and/or right singular vectors.

Syntax

```
call psgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, info)

call pdgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, info)

call pcgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, rwork, info)

call pzgesvd(jobu, jobvt, m, n, a, ia, ja, desca, s, u, iu, ju, descu, vt, ivt, jvt,
descvt, work, lwork, rwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?gesvd routine computes the singular value decomposition (SVD) of an m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U^* \Sigma V^T,$$

where Σ is an m -by- n matrix that is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A and the columns of U and V are the corresponding right and left singular vectors, respectively. The singular values are returned in array s in decreasing order and only the first $\min(m,n)$ columns of U and rows of $vt = V^T$ are computed.

Input Parameters

mp = number of local rows in A and U

nq = number of local columns in A and VT

size = $\min(m, n)$

sizeq = number of local columns in U

sizep = number of local rows in VT

jobu (global) CHARACTER*1. Specifies options for computing all or part of the matrix U .

If *jobu* = 'V', the first *size* columns of U (the left singular vectors) are returned in the array *u*;

If *jobu* = 'N', no columns of U (no left singular vectors) are computed.

jobvt (global) CHARACTER*1.

Specifies options for computing all or part of the matrix V^T .

If *jobvt* = 'V', the first *size* rows of V^T (the right singular vectors) are returned in the array *vt*;

If $jobvt = 'N'$, no rows of V^T (no right singular vectors) are computed.

m
 (global) INTEGER. The number of rows of the matrix A ($m \geq 0$).

n
 (global) INTEGER. The number of columns in A ($n \geq 0$).

a
 (local). REAL for psgesvd
 DOUBLE PRECISION for pdgesvd
 COMPLEX for pcgesvd
 COMPLEX*16 for pzgesvd
 Block cyclic array, global dimension (m, n), local dimension (mp, nq).
work(lwork) is a workspace array.

ia, ja
 (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix A , respectively.

desca
 (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix A .

iu, ju
 (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix U , respectively.

descu
 (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix U .

ivt, jvt
 (global) INTEGER. The row and column indices in the global array *vt* indicating the first row and the first column of the submatrix VT , respectively.

descvt
 (global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix VT .

work
 (local). REAL for psgesvd
 DOUBLE PRECISION for pdgesvd
 COMPLEX for pcgesvd
 COMPLEX*16 for pzgesvd
 Workspace array, dimension (*lwork*)

lwork
 (local) INTEGER. The dimension of the array *work*;
 $lwork > 2 + 6 * sizeb + \max(watobd, wbdtosvd)$,
 where *sizeb* = $\max(m, n)$, and *watobd* and *wbdtosvd* refer, respectively, to the workspace required to bidiagonalize the matrix A and to go from the bidiagonal matrix to the singular value decomposition $U S VT$.
 For *watobd*, the following holds:
 $watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared2d, wp?lared1d))$,
 where *wp?lange*, *wp?lared1d*, *wp?lared2d*, *wp?gebrd* are the workspaces required respectively for the subprograms *p?lange*, *p?lared1d*, *p?lared2d*, *p?gebrd*. Using the standard notation
 $mp = \text{numroc}(m, mb, \text{MYROW}, \text{desca}(\text{ctxt}_{}), \text{NPROW})$,
 $nq = \text{numroc}(n, nb, \text{MYCOL}, \text{desca}(lld_{}), \text{NPCOL})$,
 the workspaces required for the above subprograms are
 $wp?lange = mp$,
 $wp?lared1d = nq0$,
 $wp?lared2d = mp0$,
 $wp?gebrd = nb * (mp + nq + 1) + nq$,
 where *nq0* and *mp0* refer, respectively, to the values obtained at *MYCOL* = 0 and *MYROW* = 0. In general, the upper limit for the workspace is given by a workspace required on processor (0,0):
 $watobd \leq nb * (mp0 + nq0 + 1) + nq0$.

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For `wbdtosvd`, the following holds:

$wbdtosvd = \text{size} * (\text{wantu} * \text{nru} + \text{wantvt} * \text{ncvt}) + \max(w?bdsqr,$
 $\max(\text{wantu} * \text{wp?ormbrqln}, \text{wantvt} * \text{wp?ormbrprt}))$,

where

$\text{wantu}(\text{wantvt}) = 1$, if left/right singular vectors are wanted, and
 $\text{wantu}(\text{wantvt}) = 0$, otherwise. $w?bdsqr$, wp?ormbrqln , and wp?ormbrprt refer respectively to the workspace required for the subprograms `?bdsqr`, `p?ormbr(qln)`, and `p?ormbr(prt)`, where `qln` and `prt` are the values of the arguments `vect`, `side`, and `trans` in the call to `p?ormbr`. `nru` is equal to the local number of rows of the matrix `U` when distributed 1-dimensional "column" of processes. Analogously, `ncvt` is equal to the local number of columns of the matrix `VT` when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure `?bdsqr` requires

$w?bdsqr = \max(1, 2 * \text{size} + (2 * \text{size} - 4) * \max(\text{wantu}, \text{wantvt}))$ on every processor. Finally,

$\text{wp?ormbrqln} = \max((\text{nb} * (\text{nb}-1)) / 2, (\text{sizeq} + \text{mp}) * \text{nb}) + \text{nb} * \text{nb}$,
 $\text{wp?ormbrprt} = \max((\text{mb} * (\text{mb}-1)) / 2, (\text{sizep} + \text{nq}) * \text{mb}) + \text{mb} * \text{mb}$,

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum size for the work array. The required workspace is returned as the first element of `work` and no error message is issued by `pxerbla`.

`rwork`

REAL for `psgesvd`
 DOUBLE PRECISION for `pdgesvd`
 COMPLEX for `pcgesvd`
 COMPLEX*16 for `pzgesvd`
 Workspace array, dimension $(1 + 4 * \text{sizeb})$

Output Parameters

`a`

On exit, the contents of `a` are destroyed.

`s`

(global). REAL for `psgesvd`
 DOUBLE PRECISION for `pdgesvd`
 COMPLEX for `pcgesvd`
 COMPLEX*16 for `pzgesvd`
 Array, DIMENSION (`size`).

Contains the singular values of `A` sorted so that $s(i) \geq s(i+1)$.

`u`

(local). REAL for `psgesvd`
 DOUBLE PRECISION for `pdgesvd`
 COMPLEX for `pcgesvd`
 COMPLEX*16 for `pzgesvd`
 local dimension (`mp, sizeq`), global dimension (`m, size`)
 If `jobu = 'V'`, `u` contains the first $\min(m, n)$ columns of `U`.
 If `jobu = 'N'` or `'O'`, `u` is not referenced.

`vt`

(local). REAL for `psgesvd`
 DOUBLE PRECISION for `pdgesvd`
 COMPLEX for `pcgesvd`
 COMPLEX*16 for `pzgesvd`
 local dimension (`sizep, nq`), global dimension (`size, n`)
 If `jobvt = 'V'`, `vt` contains the first `size` rows of V^T . If `jobu = 'N'`, `vt` is not referenced.

<i>work</i>	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i>	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required size of <i>rwork</i> .
<i>info</i>	(global) INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value. If <i>info</i> > 0 <i>i</i> , then if ?bdsqr did not converge, If <i>info</i> = min(<i>m</i> , <i>n</i>) + 1, then p?gesvd has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from p?gesvd cannot be guaranteed.

vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, iwork, liwork,
ifail, iclustr, gap, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?sygvx routine computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * \mathbf{x} = \lambda * \text{sub}(B) * \mathbf{x}, \text{sub}(A) \text{ sub}(B) * \mathbf{x} = \lambda * \mathbf{x}, \text{or } \text{sub}(B) * \text{sub}(A) * \mathbf{x} = \lambda * \mathbf{x}.$$

Here \mathbf{x} denotes eigen vectors, λ (*lambda*) denotes eigenvalues, $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ is assumed to symmetric, and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * \mathbf{x} = \lambda * \text{sub}(B) * \mathbf{x}$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * \mathbf{x} = \lambda * \mathbf{x}$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * \mathbf{x} = \lambda * \mathbf{x}$.
<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> ='N', then compute eigenvalues only. If <i>jobz</i> ='V', then compute eigenvalues and eigenvectors.

<i>range</i>	(global). CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues in the interval: [<i>vl</i> , <i>vu</i>] If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i> .
<i>uplo</i>	(global). CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of sub(<i>A</i>) and sub(<i>B</i>); If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of sub(<i>A</i>) and sub(<i>B</i>).
<i>n</i>	(global). INTEGER. The order of the matrices sub(<i>A</i>) and sub (<i>B</i>), <i>n</i> \geq 0.
<i>a</i>	(local) REAL for pssygvx DOUBLE PRECISION for pdsygvx. Pointer into the local memory to an array of dimension (<i>lld_a</i> , <i>LOCc(ja</i> + <i>n</i> -1)). On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> . If <i>desca(ctxt_)</i> is incorrect, p?sygvx cannot guarantee correct error reporting.
<i>b</i>	(local). REAL for pssygvx DOUBLE PRECISION for pdsygvx. Pointer into the local memory to an array of dimension (<i>lld_b</i> , <i>LOCc(jb</i> + <i>n</i> -1)). On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric distributed matrix sub(<i>B</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>B</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>B</i>) contains the lower triangular part of the matrix.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>b</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, dimension (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> . <i>descb(ctxt_)</i> must be equal to <i>desca(ctxt_)</i> .
<i>vl, vu</i>	(global) REAL for pssygvx DOUBLE PRECISION for pdsygvx. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global) INTEGER.

If $\text{range} = \text{'I'}$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$
 If $\text{range} = \text{'A'}$ or 'V' , il and iu are not referenced.

abstol

(global)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

If $\text{jobz} = \text{'V'}$, setting *abstol* to $\text{p?lamch(context, 'U')}$ yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$\text{abstol} + \text{eps} * \max(|a|, |b|)$,

where *eps* is the machine precision. If *abstol* is less than or equal to zero, then $\text{eps} * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form.

Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{p?lamch('S')}$ not zero. If this routine returns with $((\text{mod}(\text{info}, 2).ne.0).or.*(\text{mod}(\text{info}/8, 2).ne.0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting *abstol* to $2 * \text{p?lamch('S')}$.

orfac

(global).

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $\text{tol} = \text{orfac} * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), *tol* may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0e-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) INTEGER. The row and column indices in the global array *z* indicating the first row and the first column of the submatrix *Z*, respectively.

descz

(global and local) INTEGER array, dimension (*dlen_*). The array descriptor for the distributed matrix *Z*. *descz(ctxt_)* must equal *desca(ctxt_)*.

work

(local)

REAL for pssygvx

DOUBLE PRECISION for pdsygvx.

Workspace array, dimension (*lwork*)

lwork

(local) INTEGER.

Dimension of the array *work*. See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested ($\text{jobz} = \text{'N'}$), then $\text{lwork} \geq 5 * n + \max(5 * nn, \text{NB} * (np0 + 1))$.

If eigenvectors are requested ($\text{jobz} = \text{'V'}$), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$\text{lwork} \geq 5 * n + \max(5 * nn, np0 * mq0 + 2 * nb * nb) + \text{ceil(neig, NPROW} * \text{NPCOL}) * nn$.

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to *lwork*:

$(\text{clustersize}-1) * n$,

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

```
{w(k), ..., w(k+clustersize-1)|w(j+1) ≤ w(j) +  
orfac*2*norm(A)}
```

Variable definitions:

```
neig = number of eigenvectors requested,  
nb = desca(mb_) = desca(nb_) = descz(mb_) = descz(nb_),  
nn = max(n, nb, 2),  
desca(rsrc_) = desca(nb_) = descz(rsrc_) = descz(csdc_) = 0,  
np0 = numroc(nn, nb, 0, 0, NPROW),  
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL)
```

ceil(x, y) is a ScalAPACK function returning ceiling(*x/y*)

If *lwork* is too small to guarantee orthogonality, p?syevx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*'V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, p?sygvx computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

lwork ≥ max(*lwork*, 5*n + nsytrd_lwopt, nsygst_lwopt), where *lwork*, as defined previously, depends upon the number of eigenvectors requested, and

```
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps+3)*nps
```

```
nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb
```

```
anb = pjlaenv(desca(ctxt_), 3, p?sytrd ', 'L', 0, 0, 0, 0)
```

```
sqnpcl = int(sqrt(db1e(NPROW * NPCOL)))
```

```
nps = max(numroc(n, 1, 0, 0, sqnpcl), 2*anb)
```

```
NB = desca(mb_)
```

```
np0 = numroc(n, nb, 0, 0, NPROW)
```

```
nq0 = numroc(n, nb, 0, 0, NPCOL)
```

numroc is a ScalAPACK tool functions;

pjlaenv is a ScalAPACK environmental inquiry function

MYROW, MYCOL, NPROW and NPCOL can be determined by calling the subroutine blacs_gridinfo.

For large *n*, no extra workspace is needed, however the biggest boost in performance comes for small *n*, so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If *clustersize* ≥ *n/sqrt(NPROW*NPCOL)*, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, *clustersize* = *n-1*) p?stein will perform no better than ?stein on a single processor.

For *clustersize* = *n/sqrt(NPROW*NPCOL)* reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For *clustersize* > *n/sqrt(NPROW*NPCOL)* execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxerbla.

$iwork$

(local) INTEGER. Workspace array.

$liwork$

(local) INTEGER, dimension of $iwork$.

$liwork \geq 6*nnp$

Where:

$nnp = \max(n, \text{NPROW} * \text{NPCOL} + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla.

Output Parameters

a

On exit,

If $jobz = 'V'$, and if $info = 0$, $\text{sub}(A)$ contains the distributed matrix Z of eigenvectors. The eigenvectors are normalized as follows:

```
for ibtype = 1 or 2,  $Z^T * \text{sub}(B) * Z = i$ ;
for ibtype = 3,  $Z^T * \text{inv}(\text{sub}(B)) * Z = i$ .
```

If $jobz = 'N'$, then on exit the upper triangle (if $uplo='U'$) or the lower triangle (if $uplo='L'$) of $\text{sub}(A)$, including the diagonal, is destroyed.

b

On exit, if $info \leq n$, the part of $\text{sub}(B)$ containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^T * U$ or $\text{sub}(B) = L * L^T$.

m

(global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

nz

(global) INTEGER.

Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of Z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and p?sygvy is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in Z (m.le.descz(n_)) and sufficient workspace to compute them. (See $lwork$ below.) p?sygvy is always able to detect insufficient space without computation unless range.eq. 'V'.

w

(global)

REAL for pssygvx

DOUBLE PRECISION for pdsgv.

Array, DIMENSION (n). On normal exit, the first m entries contain the selected eigenvalues in ascending order.

z

(local).

REAL for pssygvx

DOUBLE PRECISION for pdsgv.

global dimension (n, n), local dimension ($lld_z, LOCC(jz+n-1)$).

If $jobz = 'V'$, then on normal exit the first m columns of Z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

work
 If $jobz='N'$ $work(1)$ = optimal amount of workspace required to compute eigenvalues efficiently
 If $jobz = 'V'$ $work(1)$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.
 If $range='V'$, it is assumed that all eigenvectors may be required.

ifail
 (global) INTEGER.
 Array, DIMENSION (n).
ifail provides additional information when $info.ne.0$
 If $(mod(info/16,2).ne.0)$ then *ifail*(1) indicates the order of the smallest minor which is not positive definite. If $(mod(info,2).ne.0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.
 If neither of the above error conditions hold and $jobz = 'V'$, then the first m elements of *ifail* are set to zero.

iclustr
 (global) INTEGER.
 Array, DIMENSION ($2*NPROW*NPCOL$). This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*($2*i-1$) to *iclustr*($2*i$), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr()* is a zero terminated array.
 $(iclustr(2*k).ne.0 \text{ and } iclustr(2*k+1).eq.0)$ if and only if k is the number of clusters *iclustr* is not referenced if $jobz = 'N'$.

gap
 (global)
 REAL for *pssygvx*
 DOUBLE PRECISION for *pdsygvx*.
 Array, DIMENSION ($NPROW*NPCOL$). This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n)/gap(i)$, where C is a small constant.

info
 (global) INTEGER.
 If $info = 0$, the execution is successful.
 If $info < 0$: the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.
 If $info > 0$:
 If $(mod(info,2).ne.0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.
 If $(mod(info,2,2).ne.0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.
 If $(mod(info/4,2).ne.0)$, then space limit prevented *p?sygvx* from computing all of the eigenvectors between *vl* and *. The number of eigenvectors computed is returned in *nz*.
 If $(mod(info/8,2).ne.0)$, then *p?stebz* failed to compute eigenvalues.*

If $(\text{mod}(info/16, 2) \neq 0)$, then B was not positive definite. $ifail(1)$ indicates the order of the smallest minor which is not positive definite.

p?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian definite eigenproblem.

Syntax

```
call pchegvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb, vl,
vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork,
iwork, liwork, ifail, iclustr, gap, info)

call pzhegvx(ibtype, jobz, range, uplo, n, a, ia, ja, desca, b, ib, jb, descb, vl,
vu, il, iu, abstol, m, nz, w, orfac, z, iz, jz, descz, work, lwork, rwork, lrwork,
iwork, liwork, ifail, iclustr, gap, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?hegvx routine computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \quad \text{sub}(A) * \text{sub}(B) * x = \lambda * x, \quad \text{or} \quad \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ and $\text{sub}(B)$ are assumed to be Hermitian and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Input Parameters

<i>ibtype</i>	(global) INTEGER. Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \lambda * \text{sub}(B) * x;$ If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \lambda * x;$ If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \lambda * x.$
<i>jobz</i>	(global). CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> ='N', then compute eigenvalues only. If <i>jobz</i> ='V', then compute eigenvalues and eigenvectors.
<i>range</i>	(global). CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues in the interval: [vl, vu] If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> through <i>iu</i> .
<i>uplo</i>	(global). CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$;

If $uplo = 'L'$, arrays a and b store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$.

n (global). INTEGER.
The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).

a (local)
COMPLEX for `pchegvx`
DOUBLE COMPLEX for `pzhegvx`.
Pointer into the local memory to an array of dimension (lld_a , $LOCc(ja + n - 1)$). On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix $\text{sub}(A)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.

ia, ja (global) INTEGER.
The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

$desca$ (global and local) INTEGER array, dimension ($dlen_$).
The array descriptor for the distributed matrix A . If $desca(ctxt_)$ is incorrect, `phegvx` cannot guarantee correct error reporting.

b (local).
COMPLEX for `pchegvx`
DOUBLE COMPLEX for `pzhegvx`.
Pointer into the local memory to an array of dimension (lld_b , $LOCc(jb + n - 1)$). On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix $\text{sub}(B)$.
If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(B)$ contains the upper triangular part of the matrix.
If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(B)$ contains the lower triangular part of the matrix.

ib, jb (global) INTEGER.
The row and column indices in the global array b indicating the first row and the first column of the submatrix B , respectively.

$descb$ (global and local) INTEGER array, dimension ($dlen_$).
The array descriptor for the distributed matrix B . $descb(ctxt_)$ must be equal to $desca(ctxt_)$.

vl, vu (global)
REAL for `pchegvx`
DOUBLE PRECISION for `pzhegvx`.
If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.
If $range = 'A'$ or ' I' , vl and vu are not referenced.

il, iu (global)
INTEGER.
If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$.
If $range = 'A'$ or ' V' , il and iu are not referenced.

$abstol$ (global)
REAL for `pchegvx`
DOUBLE PRECISION for `pzhegvx`.

If `jobz='V'`, setting `abstol` to `p?lamch(context, 'U')` yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$abstol + \text{eps} * \max(|a|, |b|)$,

where `eps` is the machine precision. If `abstol` is less than or equal to zero, then `eps * norm(T)` will be used in its place, where `norm(T)` is the 1-norm of the tridiagonal matrix obtained by reducing `A` to tridiagonal form.

Eigenvalues will be computed most accurately when `abstol` is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this routine returns with `((mod(info, 2).ne.0).or. * (mod(info/8, 2).ne.0))`, indicating that some eigenvalues or eigenvectors did not converge, try setting `abstol` to $2 * p?lamch('S')$.

`orfac`

(global).

REAL for `pchegvx`

DOUBLE PRECISION for `pzhegvx`.

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within `tol=orfac*norm(A)` of each other are to be reorthogonalized. However, if the workspace is insufficient (see `lwork`), `tol` may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if `orfac` equals zero. A default value of 1.0E-3 is used if `orfac` is negative. `orfac` should be identical on all processes.

`iz, jz`

(global) INTEGER. The row and column indices in the global array `z` indicating the first row and the first column of the submatrix `Z`, respectively.

`descz`

(global and local) INTEGER array, dimension (`dlen_`). The array descriptor for the distributed matrix `Z`. `descz(ctxt_)` must equal `desca(ctxt_)`.

`work`

(local)

COMPLEX for `pchegvx`

DOUBLE COMPLEX for `pzhegvx`.

Workspace array, dimension (`lwork`)

`lwork`

(local).

INTEGER. The dimension of the array `work`.

If only eigenvalues are requested:

$lwork \geq n + \max(NB * (np0 + 1), 3)$

If eigenvectors are requested:

$lwork \geq n + (np0 + mq0 + NB) * NB$

with `mq0 = numroc(nn, NB, 0, 0, NPCOL)`.

For optimal performance, greater workspace is needed, that is

$lwork \geq \max(lwork, n, nhetrnd_lwopt, nhegst_lwopt)$

where `lwork` is as defined above, and

$nhetrnd_lwork = 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps;$

$nhegst_lwopt = 2 * np0 * nb + nq0 * nb + nb * nb$

$nb = desca(mb_)$

$np0 = numroc(n, nb, 0, 0, NPROW)$

$nq0 = numroc(n, nb, 0, 0, NPCOL)$

$ictxt = desca(ctxt_)$

$anb = pjlaenv(ictxt, 3, 'p?hetrd', 'L', 0, 0, 0, 0)$

$sqrnpc = sqrt(dble(NPROW * NPCOL))$

$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 * anb)$

numroc is a ScaLAPACK tool functions;
 pjlaenv is a ScaLAPACK environmental inquiry function MYROW, MYCOL,
 NPROW and NPCOL can be determined by calling the subroutine
 blacs_gridinfo.
 If *lwork* = -1, then *lwork* is global input and a workspace query is
 assumed; the routine only calculates the size required for optimal
 performance for all work arrays. Each of these values is returned in the first
 entry of the corresponding work arrays, and no error message is issued by
 pxerbla.

rwork
 (local)
 REAL for pchegvx
 DOUBLE PRECISION for pzhegvx.
 Workspace array, DIMENSION (*lrwork*).
lrwork
 (local) INTEGER. The dimension of the array *rwork*.
 See below for definitions of variables used to define *lrwork*.
 If no eigenvectors are requested (*jobz* = 'N'), then *lrwork* $\geq 5*nn+4*n$
 If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace
 required to guarantee that all eigenvectors are computed is:

$$\text{lrwork} \geq 4*n + \max(5*nn, np0*mq0) + \text{ceil}(neig, \\ \text{NPROW*NPCOL}) * nn$$
 The computed eigenvectors may not be orthogonal if the minimal
 workspace is supplied and *orfac* is too small. If you want to guarantee
 orthogonality (at the cost of potentially poor performance) you should add
 the following value to *lrwork*:

$$(\text{clustersize}-1)*n,$$
 where *clustersize* is the number of eigenvalues in the largest cluster,
 where a cluster is defined as a set of close eigenvalues:

$$\{w(k), \dots, w(k+\text{clustersize}-1) | w(j+1) \leq w(j) + \text{orfac} * 2 * \text{norm}(A)\}$$
 Variable definitions:

$$\begin{aligned} neig &= \text{number of eigenvectors requested;} \\ nb &= \text{descza(mb)} = \text{descza(nb)} = \text{descza(mb)} = \text{descza(nb)}; \\ nn &= \max(n, nb, 2); \\ \text{descza(rsrc)} &= \text{descza(nb)} = \text{descza(rsrc)} = \text{descza(csra)} = 0; \\ np0 &= \text{numroc}(nn, nb, 0, 0, \text{NPROW}); \\ mq0 &= \text{numroc}(\max(neig, nb, 2), nb, 0, 0, \text{NPCOL}); \\ \text{ceil}(x, y) &\text{ is a ScaLAPACK function returning ceiling}(x/y). \end{aligned}$$
 When *lrwork* is too small:
 If *lwork* is too small to guarantee orthogonality, p?hegvx attempts to
 maintain orthogonality in the clusters with the smallest spacing between the
 eigenvalues.
 If *lwork* is too small to compute all the eigenvectors requested, no
 computation is performed and *info*= -25 is returned. Note that when
range='V', p?hegvx does not know how many eigenvectors are requested
 until the eigenvalues are computed. Therefore, when *range*='V' and as
 long as *lwork* is large enough to allow p?hegvx to compute the
 eigenvalues, p?hegvx will compute the eigenvalues and as many
 eigenvectors as it can.
 Relationship between workspace, orthogonality & performance:
 If *clustersize* $> n/\sqrt{\text{NPROW*NPCOL}}$, then providing enough space
 to compute all the eigenvectors orthogonally will cause serious degradation
 in performance. In the limit (that is, *clustersize* = *n*-1) p?stein will
 perform no better than ?stein on 1 processor.

For $\text{clustersize} = n/\sqrt{\text{NPROW} \times \text{NPCOL}}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $\text{clustersize} > n/\sqrt{\text{NPROW} \times \text{NPCOL}}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $\text{lwork} = -1$, then lrwork is global input and a workspace query is assumed; the routine only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pzerbla`.

iwork

(local) INTEGER. Workspace array.

liwork

(local) INTEGER, dimension of *iwork*.

$\text{liwork} \geq 6 * \text{nnp}$

Where: $\text{nnp} = \max(n, \text{NPROW} * \text{NPCOL} + 1, 4)$

If $\text{liwork} = -1$, then liwork is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pzerbla`.

Output Parameters

a

On exit, if $\text{jobz} = 'V'$, then if $\text{info} = 0$, $\text{sub}(A)$ contains the distributed matrix Z of eigenvectors.

The eigenvectors are normalized as follows:

If $\text{ibtype} = 1$ or 2 , then $Z^H * \text{sub}(B) * Z = I$;

If $\text{ibtype} = 3$, then $Z^H * \text{inv}(\text{sub}(B)) * Z = I$.

If $\text{jobz} = 'N'$, then on exit the upper triangle (if $\text{uplo}='U'$) or the lower triangle (if $\text{uplo}='L'$) of $\text{sub}(A)$, including the diagonal, is destroyed.

b

On exit, if $\text{info} \leq n$, the part of $\text{sub}(B)$ containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^H * U$, or $\text{sub}(B) = L * L^H$.

m

(global) INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.

nz

(global) INTEGER. Total number of eigenvectors computed. $0 < nz < m$.

The number of columns of Z that are filled.

If $\text{jobz} \neq 'V'$, nz is not referenced.

If $\text{jobz} = 'V'$, $nz = m$ unless the user supplies insufficient space and `p?hegvx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in Z (*m*. i.e. `descz(n_)`) and sufficient workspace to compute them. (See `lwork` below.) The routine `p?hegvx` is always able to detect insufficient space without computation unless `range = 'V'`.

w

(global)

REAL for `pchegvx`

DOUBLE PRECISION for `pzhegvx`.

Array, DIMENSION (*n*). On normal exit, the first *m* entries contain the selected eigenvalues in ascending order.

z

(local).

COMPLEX for `pchegvx`

DOUBLE COMPLEX for `pzhegvx`.

global dimension (*n*, *n*), local dimension (*lld_z*, `LOCc(jz+n-1)`).

If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

work

On exit, $work(1)$ returns the optimal amount of workspace.

rwork

On exit, $rwork(1)$ contains the amount of workspace required for optimal efficiency

If $jobz='N'$ $rwork(1)$ = optimal amount of workspace required to compute eigenvalues efficiently

If $jobz='V'$ $rwork(1)$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If $range='V'$, it is assumed that all eigenvectors may be required when computing optimal workspace.

ifail

(global) INTEGER.

Array, DIMENSION (n).

ifail provides additional information when $info.ne.0$

If $(mod(info/16,2).ne.0)$, then $ifail(1)$ indicates the order of the smallest minor which is not positive definite.

If $(mod(info,2).ne.0)$ on exit, then $ifail(1)$ contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions are held, and $jobz = 'V'$, then the first m elements of *ifail* are set to zero.

iclustr

(global) INTEGER.

Array, DIMENSION $(2*NPROW*NPCOL)$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr(2*i-1)$ to $iclustr(2*i)$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

iclustr() is a zero terminated array. $(iclustr(2*k).ne.$

$0.\text{and}.clustr(2*k+1).\text{eq.}0)$ if and only if k is the number of clusters.

iclustr is not referenced if $jobz = 'N'$.

gap

(global)

REAL for *pchegvx*

DOUBLE PRECISION for *pzhgevx*.

Array, DIMENSION $(NPROW*NPCOL)$.

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n)/gap(i)$, where C is a small constant.

info

(global) INTEGER.

If $info = 0$, the execution is successful.

If $info < 0$: the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $(\text{mod}(info, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(info, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented p?sygsvx from computing all of the eigenvectors between *vl* and *. The number of eigenvectors computed is returned in *nz*.*

If $(\text{mod}(info/8, 2) \neq 0)$, then p?stebz failed to compute eigenvalues.

If $(\text{mod}(info/16, 2) \neq 0)$, then *B* was not positive definite. *ifail(1)* indicates the order of the smallest minor which is not positive definite.

ScaLAPACK Auxiliary and Utility Routines

7

This chapter describes the Intel® Math Kernel Library implementation of ScaLAPACK [Auxiliary Routines](#) and [Utility Functions and Routines](#). The library includes routines for both real and complex data.

NOTE ScaLAPACK routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Routine naming conventions, mathematical notation, and matrix storage schemes used for ScaLAPACK auxiliary and utility routines are the same as described in previous chapters. Some routines and functions may have combined character codes, such as `sc` or `dz`. For example, the routine `psum1` uses a complex input array and returns a real value.

Auxiliary Routines

ScaLAPACK Auxiliary Routines

Routine Name	Data Types	Description
<code>p?lacgv</code>	<code>c, z</code>	Conjugates a complex vector.
<code>p?max1</code>	<code>c, z</code>	Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS <code>pamax</code> , but using the absolute value to the real part).
<code>?combamax1</code>	<code>c, z</code>	Finds the element with maximum real part absolute value and its corresponding global index.
<code>p?sum1</code>	<code>sc, dz</code>	Forms the 1-norm of a complex vector similar to Level 1 PBLAS <code>p?asum</code> , but using the true absolute value.
<code>p?dbtrsv</code>	<code>s, d, c, z</code>	Computes an LU factorization of a general tridiagonal matrix with no pivoting. The routine is called by <code>p?dbtrs</code> .
<code>p?dttrsv</code>	<code>s, d, c, z</code>	Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by <code>p?dttrs</code> .
<code>p?gebd2</code>	<code>s, d, c, z</code>	Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).
<code>p?gehd2</code>	<code>s, d, c, z</code>	Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).
<code>p?gelq2</code>	<code>s, d, c, z</code>	Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).
<code>p?geql2</code>	<code>s, d, c, z</code>	Computes a QL factorization of a general rectangular matrix (unblocked algorithm).
<code>p?geqr2</code>	<code>s, d, c, z</code>	Computes a QR factorization of a general rectangular matrix (unblocked algorithm).
<code>p?gerq2</code>	<code>s, d, c, z</code>	Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).

Routine Name	Data Types	Description
p?getf2	s, d, c, z	Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).
p?labrd	s, d, c, z	Reduces the first nb rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?lacon	s, d, c, z	Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.
p?laconsb	s, d	Looks for two consecutive small subdiagonal elements.
p?lacp2	s, d, c, z	Copies all or part of a distributed matrix to another distributed matrix.
p?lacp3	s, d	Copies from a global parallel array into a local replicated array or vice versa.
p?lacpy	s, d, c, z	Copies all or part of one two-dimensional array to another.
p?laevswp	s, d, c, z	Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.
p?lahrd	s, d, c, z	Reduces the first nb columns of a general rectangular matrix A so that elements below the k^{th} subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?laiect	s, d, c, z	Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).
p?lange	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.
p?lanhs	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.
p?lansy, p?lanhe	s, d, c, z / c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.
p?lantr	s, d, c, z	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.
p?lapiv	s, d, c, z	Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.
p?lagge	s, d, c, z	Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.
p?laqsy	s, d, c, z	Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.
p?lared1d	s, d	Redistributes an array assuming that the input array $bycol$ is distributed across rows and that all process columns contain the same copy of $bycol$.

Routine Name	Data Types	Description
p?lared2d	s, d	Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> .
p?larf	s, d, c, z	Applies an elementary reflector to a general rectangular matrix.
p?larfb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
p?larfc	c, z	Applies the conjugate transpose of an elementary reflector to a general matrix.
p?larfg	s, d, c, z	Generates an elementary reflector (Householder matrix).
p?larft	s, d, c, z	Forms the triangular vector <i>T</i> of a block reflector $H=I-VTV^H$
p?larz	s, d, c, z	Applies an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzb	s, d, c, z	Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.
p?larzc	c, z	Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzt	s, d, c, z	Forms the triangular factor <i>T</i> of a block reflector $H=I-VTV^H$ as returned by p?tzrzf.
p?lascl	s, d, c, z	Multiplies a general rectangular matrix by a real scalar defined as $C_{\text{to}}/C_{\text{from}}$.
p?laset	s, d, c, z	Initializes the off-diagonal elements of a matrix to α and the diagonal elements to β .
p?lasmsub	s, d	Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.
p?lassq	s, d, c, z	Updates a sum of squares represented in scaled form.
p?laswp	s, d, c, z	Performs a series of row interchanges on a general rectangular matrix.
p?latra	s, d, c, z	Computes the trace of a general square distributed matrix.
p?latrd	s, d, c, z	Reduces the first <i>nb</i> rows and columns of a symmetric/Hermitian matrix <i>A</i> to real tridiagonal form by an orthogonal/unitary similarity transformation.
p?latrz	s, d, c, z	Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.
p?lauu2	s, d, c, z	Computes the product UU^H or LL^H , where <i>U</i> and <i>L</i> are upper or lower triangular matrices (local unblocked algorithm).
p?laum	s, d, c, z	Computes the product UU^H or LL^H , where <i>U</i> and <i>L</i> are upper or lower triangular matrices.
p?lawil	s, d	Forms the Wilkinson transform.
p?org2l/p?ung2l	s, d, c, z	Generates all or part of the orthogonal/unitary matrix <i>Q</i> from a <i>QL</i> factorization determined by p?geqlf (unblocked algorithm).

Routine Name	Data Types	Description
p?org2r/p?ung2r	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orgl2/p?ungl2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).
p?orgr2/p?ungr2	s, d, c, z	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?orm2l/p?unm2l	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).
p?orm2r/p?unm2r	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orml2/p?unml2	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).
p?ormr2/p?unmr2	s, d, c, z	Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?pbtrsv	s, d, c, z	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf.
p?pttrsv	s, d, c, z	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf.
p?potf2	s, d, c, z	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).
p?rscl	s, d, cs, zd	Multiplies a vector by the reciprocal of a real scalar.
p?srgs2/p?hegs2	s, d, c, z	Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).
p?syt2/p?hetd2	s, d, c, z	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).
p?trti2	s, d, c, z	Computes the inverse of a triangular matrix (local unblocked algorithm).
?lamsh	s, d	Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.
?laref	s, d	Applies Householder reflectors to matrices on either their rows or columns.
?lasorte	s, d	Sorts eigenpairs by real and complex data types.
?lasrt2	s, d	Sorts numbers in increasing or decreasing order.
?stein2	s, d	Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.
?dbtf2	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Routine Name	Data Types	Description
?dbtrf	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).
?dttrf	s, d, c, z	Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).
?dttrs v	s, d, c, z	Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.
?pttrs v	s, d, c, z	Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the LDL^H factorization computed by ?pttrf.
?steqr2	s, d	Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

p?lacgv

Conjugates a complex vector.

Syntax

```
call pclacgv(n, x, ix, jx, descx, incx)
call pzlacgv(n, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lacgv routine conjugates a complex vector $\text{sub}(x)$ of length n , where $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix:ix+n-1, jx)$ if $incx = 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of the distributed vector $\text{sub}(x)$.
<i>x</i>	(local). COMPLEX for pclacgv COMPLEX*16 for pzlacgv. Pointer into the local memory to an array of DIMENSION (<i>lld_x</i> , *). On entry the vector to be conjugated $x(i) = X(ix + (jx-1)*m_x + (i-1)*incx), 1 \leq i \leq n$.
<i>ix</i>	(global) INTEGER. The row index in the global array <i>x</i> indicating the first row of $\text{sub}(x)$.
<i>jx</i>	(global) INTEGER. The column index in the global array <i>x</i> indicating the first column of $\text{sub}(x)$.
<i>descx</i>	(global and local) INTEGER, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>X</i> .
<i>incx</i>	(global) INTEGER. The global increment for the elements of <i>x</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

x (local).
On exit, the conjugated vector.

p?max1

Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS p?amax, but using the absolute value to the real part).

Syntax

```
call pcmax1(n, amax, indx, x, ix, jx, descx, incx)
call pzmax1(n, amax, indx, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?max1` routine computes the global index of the maximum element in absolute value of a distributed vector `sub(x)`. The global index is returned in `indx` and the value is returned in `amax`, where `sub(x)` denotes $X(ix:ix+n-1, jx)$ if `incx = 1`, $X(ix, jx:jx+n-1)$ if `incx = m_x`.

Input Parameters

n (global) pointer to INTEGER. The number of components of the distributed vector `sub(x)`. $n \geq 0$.

x (local)
COMPLEX for `pcmax1`.
COMPLEX*16 for `pzmax1`
Array containing the local pieces of a distributed matrix of dimension of at least $((jx-1)*m_x+ix+(n-1)*abs(incx))$. This array contains the entries of the distributed vector `sub(x)`.

ix (global) INTEGER. The row index in the global array `x` indicating the first row of `sub(x)`.

jx (global) INTEGER. The column index in the global array `x` indicating the first column of `sub(x)`

descx (global and local) INTEGER. Array, DIMENSION (`dlen_`). The array descriptor for the distributed matrix `X`.

incx (global) INTEGER. The global increment for the elements of `x`. Only two values of `incx` are supported in this version, namely 1 and `m_x`. `incx` must not be zero.

Output Parameters

amax (global output) pointer to REAL. The absolute value of the largest entry of the distributed vector `sub(x)` only in the scope of `sub(x)`.

indx (global output) pointer to INTEGER. The global index of the element of the distributed vector `sub(x)` whose real part has maximum absolute value.

?combamax1

Finds the element with maximum real part absolute value and its corresponding global index.

Syntax

```
call ccombamax1(v1, v2)
call zcombamax1(v1, v2)
```

Include Files

- C: mkl_scalapack.h

Description

The ?combamax1 routine finds the element having maximum real part absolute value as well as its corresponding global index.

Input Parameters

v1	(local) COMPLEX for ccombamax1 COMPLEX*16 for zcombamax1 Array, DIMENSION 2. The first maximum absolute value element and its global index. v1(1)=amax, v1(2)=indx.
v2	(local) COMPLEX for ccombamax1 COMPLEX*16 for zcombamax1 Array, DIMENSION 2. The second maximum absolute value element and its global index. v2(1)=amax, v2(2)=indx.

Output Parameters

v1	(local). The first maximum absolute value element and its global index. v1(1)=amax, v1(2)=indx.
----	---

p?sum1

Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.

Syntax

```
call pscsum1(n, asum, x, ix, jx, descx, incx)
call pdzsum1(n, asum, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_scalapack.h

Description

The p?sum1 routine returns the sum of absolute values of a complex distributed vector sub(x) in asum, where sub(x) denotes $X(ix:ix+n-1, jx:jx)$, if $incx = 1$, $X(ix:ix, jx:jx+n-1)$, if $incx = m_x$.

Based on p?asum from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

Input Parameters

<i>n</i>	(global) pointer to INTEGER. The number of components of the distributed vector $\text{sub}(x)$. $n \geq 0$.
<i>x</i>	(local) COMPLEX for pscsum1 COMPLEX*16 for pdzsum1 . Array containing the local pieces of a distributed matrix of dimension of at least $((j_x-1)*m_x+ix+(n-1)*\text{abs}(incx))$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix</i>	(global) INTEGER. The row index in the global array x indicating the first row of $\text{sub}(x)$.
<i>jx</i>	(global) INTEGER. The column index in the global array x indicating the first column of $\text{sub}(x)$
<i>descx</i>	(global and local) INTEGER. Array, DIMENSION 9. The array descriptor for the distributed matrix x .
<i>incx</i>	(global) INTEGER. The global increment for the elements of x . Only two values of <i>incx</i> are supported in this version, namely 1 and m_x .

Output Parameters

<i>asum</i>	(local) Pointer to REAL. The sum of absolute values of the distributed vector $\text{sub}(x)$ only in its scope.
-------------	---

p?dbtrsv

Computes an LU factorization of a general triangular matrix with no pivoting. The routine is called by p?
dbtrs.

Syntax

```
call psdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)

call pddbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)

call pcdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)

call pzdbtrsv(uplo, trans, n, bwl, bwu, nrhs, a, ja, desca, b, ib, descb, af, laf,  
work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?dbtrsv routine solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$ (for real flavors); $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$ (for complex flavors),

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Gaussian elimination code `PD@ (dom_pre) BTRF` and is stored in $A(1:n, ja:ja+n-1)$ and af . The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter `trans`.

Routine `p?dbtrf` must be called first.

Input Parameters

<code>uplo</code>	(global) CHARACTER. If <code>uplo='U'</code> , the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <code>uplo = 'L'</code> , the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<code>trans</code>	(global) CHARACTER. If <code>trans = 'N'</code> , solve with $A(1:n, ja:ja+n-1)$, if <code>trans = 'C'</code> , solve with conjugate transpose $A(1:n, ja:ja+n-1)$.
<code>n</code>	(global) INTEGER. The order of the distributed submatrix A ; ($n \geq 0$).
<code>bwl</code>	(global) INTEGER. Number of subdiagonals. $0 \leq bwl \leq n-1$.
<code>bwu</code>	(global) INTEGER. Number of subdiagonals. $0 \leq bwu \leq n-1$.
<code>nrhs</code>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).
<code>a</code>	(local). REAL for <code>psdbtrsv</code> DOUBLE PRECISION for <code>pddbtrsv</code> COMPLEX for <code>pcdbtrsv</code> COMPLEX*16 for <code>pzdbtrsv</code> . Pointer into the local memory to an array with first DIMENSION $l1d_a \geq (bwl + bwu + 1)$ (stored in <code>desca</code>). On entry, this array contains the local pieces of the n -by- n unsymmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<code>ja</code>	(global) INTEGER. The index in the global array <code>a</code> that points to the start of the matrix to be operated on (which may be either all of <code>a</code> or a submatrix of <code>A</code>).
<code>desca</code>	(global and local) INTEGER array of DIMENSION (<code>dlen_</code>). if 1 _d type (<code>dtype_a = 501</code> or <code>502</code>), <code>dlen \geq 7</code> ; if 2 _d type (<code>dtype_a = 1</code>), <code>dlen \geq 9</code> . The array descriptor for the distributed matrix <code>A</code> . Contains information of mapping of <code>A</code> to memory.
<code>b</code>	(local). REAL for <code>psdbtrsv</code> DOUBLE PRECISION for <code>pddbtrsv</code> COMPLEX for <code>pcdbtrsv</code> COMPLEX*16 for <code>pzdbtrsv</code> . Pointer into the local memory to an array of local lead DIMENSION $l1d_b \geq nb$. On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$.
<code>ib</code>	(global) INTEGER. The row index in the global array <code>b</code> that points to the first row of the matrix to be operated on (which may be either all of <code>b</code> or a submatrix of <code>B</code>).
<code>descb</code>	(global and local) INTEGER array of DIMENSION (<code>dlen_</code>).

if $1 \leq \text{type} (\text{dtype_b} = 502), \text{dlen} \geq 7$;
 if $2 \leq \text{type} (\text{dtype_b} = 1), \text{dlen} \geq 9$. The array descriptor for the distributed matrix B . Contains information of mapping B to memory.

laf
 (local)
 INTEGER. Size of user-input Auxiliary Filling space af .
 laf must be $\geq nb * (bwl + bwu) + 6 * \max(bwl, bwu) * \max(bwl, bwu)$. If laf is not large enough, an error code is returned and the minimum acceptable size will be returned in $af(1)$.

work
 (local).
 REAL for psdbtrsv
 DOUBLE PRECISION for pddbtrsv
 COMPLEX for pcdbtrsv
 COMPLEX*16 for pzdbtrsv.
 Temporary workspace. This space may be overwritten in between calls to routines.
 $work$ must be the size given in $lwork$.

lwork
 (local or global) INTEGER.
 Size of user-input workspace $work$. If $lwork$ is too small, the minimal acceptable size will be returned in $work(1)$ and an error code is returned.
 $lwork \geq \max(bwl, bwu) * nrhs$.

Output Parameters

a
 (local).
 This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.

b
 On exit, this contains the local piece of the solutions distributed matrix x .

af
 (local).
 REAL for psdbtrsv
 DOUBLE PRECISION for pddbtrsv
 COMPLEX for pcdbtrsv
 COMPLEX*16 for pzdbtrsv.
 Auxiliary Filling Space. Filling is created during the factorization routine $p?dbtrf$ and this is stored in af . If a linear system is to be solved using $p?dbtrf$ after the factorization routine, af must not be altered after the factorization.

work
 On exit, $work(1)$ contains the minimal $lwork$.

info
 (local).
 INTEGER. If $info = 0$, the execution is successful.
 < 0 : If the i -th argument is an array and the j -entry had an illegal value, then $info = - (i * 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?dttrs

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges.
 The routine is called by p?dttrs.

Syntax

```

call psdttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
call pddttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
call pcdttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)
call pzdttrs(uplo, trans, n, nrhs, dl, d, du, ja, desca, b, ib, descb, af, laf,
work, lwork, info)

```

Include Files

- C: mkl_scalapack.h

Description

The p?dttrs routine solves a tridiagonal triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1 :nrhs)$ or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1 :nrhs)$ for real flavors; $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1 :nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a tridiagonal matrix factor produced by the Gaussian elimination code PS@(*dom_pre*)TTRF and is stored in $A(1:n, ja:ja+n-1)$ and *af*.

The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter *trans*.

Routine p?dttrf must be called first.

Input Parameters

<i>uplo</i>	(global) CHARACTER. If <i>uplo</i> ='U', the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <i>uplo</i> = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) CHARACTER. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$, if <i>trans</i> = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix <i>A</i> ; (<i>n</i> \geq 0).
<i>nrhs</i>	(global) INTEGER. The number of right-hand sides; the number of columns of the distributed submatrix $B(ib:ib+n-1, 1:nrhs)$. (<i>nrhs</i> \geq 0).
<i>dl</i>	(local). REAL for psdttrs DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs COMPLEX*16 for pzdttrs. Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, <i>dl</i> (1) is not referenced, and <i>dl</i> must be aligned with <i>d</i> . Must be of size $\geq desca(nb_)$.
<i>d</i>	(local). REAL for psdttrs

	DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs COMPLEX*16 for pzdttrs. Pointer to local part of global vector storing the main diagonal of the matrix.
<i>du</i>	(local). REAL for psdttrs DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs COMPLEX*16 for pzdttrs. Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, <i>du</i> (<i>n</i>) is not referenced, and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) INTEGER. The index in the global array <i>a</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local). INTEGER array of DIMENSION (<i>dlen</i>). if 1 <i>d</i> type (<i>dtype_a</i> = 501 or 502), <i>dlen</i> ≥ 7; if 2 <i>d</i> type (<i>dtype_a</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>A</i> . Contains information of mapping of <i>A</i> to memory.
<i>b</i>	(local) REAL for psdttrs DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs COMPLEX*16 for pzdttrs. Pointer into the local memory to an array of local lead DIMENSION <i>l1d_b</i> ≥ <i>nb</i> . On entry, this array contains the local pieces of the right-hand sides <i>B</i> (<i>ib</i> : <i>ib</i> + <i>n</i> -1, 1 : <i>nrhs</i>).
<i>ib</i>	(global). INTEGER. The row index in the global array <i>b</i> that points to the first row of the matrix to be operated on (which may be either all of <i>b</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local). INTEGER array of DIMENSION (<i>dlen</i>). if 1 <i>d</i> type (<i>dtype_b</i> = 502), <i>dlen</i> ≥7; if 2 <i>d</i> type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix <i>B</i> . Contains information of mapping <i>B</i> to memory.
<i>laf</i>	(local). INTEGER. Size of user-input Auxiliary Filling space <i>af</i> . <i>laf</i> must be ≥ 2*(<i>nb</i> +2). If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i> (1).
<i>work</i>	(local). REAL for psdttrs DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs COMPLEX*16 for pzdttrs. Temporary workspace. This space may be overwritten in between calls to routines. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global). INTEGER.

Size of user-input workspace work . If lwork is too small, the minimal acceptable size will be returned in $\text{work}(1)$ and an error code is returned.
 $\text{lwork} \geq 10 * \text{ncol} + 4 * \text{nrhs}$.

Output Parameters

d_1	(local). On exit, this array contains information containing the factors of the matrix.
d	On exit, this array contains information containing the factors of the matrix. Must be of size $\geq \text{desca}(\text{nb}_\perp)$.
b	On exit, this contains the local piece of the solutions distributed matrix X .
af	(local). REAL for psdttrs DOUBLE PRECISION for pddttrs COMPLEX for pcdttrs COMPLEX*16 for pzdttrs . Auxiliary Filling Space. Filling is created during the factorization routine p?dttrf and this is stored in af . If a linear system is to be solved using p?dttrs after the factorization routine, af must not be altered after the factorization.
work	On exit, $\text{work}(1)$ contains the minimal lwork .
$info$	(local). INTEGER. If $info=0$, the execution is successful. if $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?gebd2

Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).

Syntax

```
call psgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pdgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pcgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
call pzgebd2(m, n, a, ia, ja, desca, d, e, tauq, taup, work, lwork, info)
```

Include Files

- C:\mkl_scalapack.h

Description

The p?gebd2 routine reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q^T * \text{sub}(A) * P = B.$$

If $m \geq n$, B is the upper bidiagonal; if $m < n$, B is the lower bidiagonal.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for <code>psgebd2</code> DOUBLE PRECISION for <code>pdgebd2</code> COMPLEX for <code>pcgebd2</code> COMPLEX*16 for <code>pzgebd2</code> . Pointer into the local memory to an array of <code>DIMENSION(1ld_a, LOCl(ja+n-1))</code> . On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for <code>psgebd2</code> DOUBLE PRECISION for <code>pdgebd2</code> COMPLEX for <code>pcgebd2</code> COMPLEX*16 for <code>pzgebd2</code> . This is a workspace array of <code>DIMENSION(lwork)</code> .
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq \max(mpa0, nqa0)$, where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb, mycol, csrc_a, npcol)$, $mpa0 = \text{numroc}(m+iroffa, nb, myrow, iarow, nprow)$, $nqa0 = \text{numroc}(n+icoffa, nb, mycol, iacol, npcol)$. <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the subroutine <code>blacs_gridinfo</code> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

Output Parameters

<i>a</i>	(local). On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix <i>B</i> ; the elements below the diagonal, with the array <i>taaq</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <i>taup</i> , represent the orthogonal matrix <i>P</i> as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix <i>B</i> ; the elements below the first subdiagonal, with the array <i>taaq</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors, and the
----------	--

elements above the diagonal, with the array τ_{aup} , represent the orthogonal matrix P as a product of elementary reflectors. See *Applications Notes* below.

d

(local)
REAL for `psgebd2`
DOUBLE PRECISION for `pdgebd2`
COMPLEX for `pcgebd2`
COMPLEX*16 for `pzgebd2`.
Array, DIMENSION $\text{LOCc}(ja+\min(m,n)-1)$ if $m \geq n$; $\text{LOCr}(ia+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d(i) = a(i,i)$. d is tied to the distributed matrix A .

e

(local)
REAL for `psgebd2`
DOUBLE PRECISION for `pdgebd2`
COMPLEX for `pcgebd2`
COMPLEX*16 for `pzgebd2`.
Array, DIMENSION $\text{LOCc}(ja+\min(m,n)-1)$ if $m \geq n$; $\text{LOCr}(ia+\min(m,n)-2)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B :
if $m \geq n$, $e(i) = a(i, i+1)$ **for** $i = 1, 2, \dots, n-1$;
if $m < n$, $e(i) = a(i+1, i)$ **for** $i = 1, 2, \dots, m-1$. e is tied to the distributed matrix A .

taug

(local).
REAL for `psgebd2`
DOUBLE PRECISION for `pdgebd2`
COMPLEX for `pcgebd2`
COMPLEX*16 for `pzgebd2`.
Array, DIMENSION $\text{LOCc}(ja+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . τ_{aup} is tied to the distributed matrix A .

taup

(local).
REAL for `psgebd2`
DOUBLE PRECISION for `pdgebd2`
COMPLEX for `pcgebd2`
COMPLEX*16 for `pzgebd2`.
Array, DIMENSION $\text{LOCr}(ia+\min(m,n)-1)$. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix P . τ_{aup} is tied to the distributed matrix A .

work

On exit, $\text{work}(1)$ returns the minimal and optimal lwork .

info

(local)
INTEGER.
If $\text{info} = 0$, the execution is successful.
if $\text{info} < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$Q = H(1)*H(2)*\dots*H(n)$, and $P = G(1)*G(2)*\dots*G(n-1)$

Each $H(i)$ and $G(i)$ has the form:

$H(i) = I - \tau_{aq}v^*v'$, and $G(i) = I - \tau_{ap}u^*u'$,

where τ_{aq} and τ_{ap} are real/complex scalars, and v and u are real/complex vectors. $v(1: i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i-ia+m-1, a+i-1);$

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1);$

τ_{aq} is stored in $TAUQ(ja+i-1)$ and τ_{ap} in $TAUP(ia+i-1)$.

If $m < n$,

$v(1: i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i+1: ia+m-1, ja+i-1);$

$u(1: i-1) = 0$, $u(i) = 1$, and $u(i+1 : n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1);$

τ_{aq} is stored in $TAUQ(ja+i-1)$ and τ_{ap} in $TAUP(ia+i-1)$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples:

$$\begin{array}{ll} m = 6 \text{ and } n = 5 (m > n) : & m = 5 \text{ and } n = 6 (m < n) : \\ \left[\begin{array}{cccc} d & e & v1 & v1 & v1 \\ v1 & d & e & v2 & v2 \\ v1 & v2 & d & e & v3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{array} \right] & \left[\begin{array}{cccccc} d & v1 & v1 & v1 & v1 & v1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{array} \right] \end{array}$$

where d and e denote diagonal and off-diagonal elements of B , v_i denotes an element of the vector defining $H(i)$, and u_i an element of the vector defining $G(i)$.

p?gehd2

Reduces a general matrix to upper Hessenberg form
by an orthogonal/unitary similarity transformation
(unblocked algorithm).

Syntax

```
call psgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pdgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pcgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
call pzgehd2(n, ilo, ihi, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?gehd2 routine reduces a real/complex general distributed matrix $\text{sub}(A)$ to upper Hessenberg form H by an orthogonal/unitary similarity transformation: $Q'^*\text{sub}(A)*Q = H$, where $\text{sub}(A) = A(ia+n-1 : ia + n-1, ja+n-1 : ja+n-1)$.

Input Parameters

<i>n</i>	(global) INTEGER. The order of the distributed submatrix A . ($n \geq 0$).
<i>ilo, ihi</i>	(global) INTEGER. It is assumed that $\text{sub}(A)$ is already upper triangular in rows $ia:ia+ilo-2$ and $ia+ihi:ia+n-1$ and columns $ja:ja+jlo-2$ and $ja+jhi:ja+n-1$. See <i>Application Notes</i> for further information. If $n \geq 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set $ilo = 1$, $ihi = n$.
<i>a</i>	(local). REAL for <code>psgehd2</code> DOUBLE PRECISION for <code>pdgehd2</code> COMPLEX for <code>pcgehd2</code> COMPLEX*16 for <code>pzgehd2</code> . Pointer into the local memory to an array of DIMENSION(lld_a , $LOCc(ja+n-1)$). On entry, this array contains the local pieces of the n -by- n general distributed matrix $\text{sub}(A)$ to be reduced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .
<i>work</i>	(local). REAL for <code>psgehd2</code> DOUBLE PRECISION for <code>pdgehd2</code> COMPLEX for <code>pcgehd2</code> COMPLEX*16 for <code>pzgehd2</code> . This is a workspace array of DIMENSION ($lwork$).
<i>lwork</i>	(local or global). INTEGER. The dimension of the array $work$. $lwork$ is local input and must be at least $lwork \geq nb + \max(npa0, nb)$, where $nb = mb_a = nb_a$, $iroffa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc_a, nprow)$, $npa0 = \text{numroc}(ihi + iroffa, nb, myrow, iarow, nprow)$. indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the subroutine <code>blacs_gridinfo</code> . If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

Output Parameters

<i>a</i>	(local). On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix H , and the elements below the first subdiagonal, with the array τ_{α} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors. (see <i>Application Notes</i> below). (local). REAL for <code>psgehd2</code> DOUBLE PRECISION for <code>pdgehd2</code> COMPLEX for <code>pcgehd2</code> COMPLEX*16 for <code>pzgehd2</code> .
<i>tau</i>	

Array, DIMENSION $\text{LOCc}(ja+n-2)$ The scalar factors of the elementary reflectors (see *Application Notes* below). Elements $ja:ja+ilo-2$ and $ja+ih:i:ja+n-2$ of τ_{au} are set to zero. τ_{au} is tied to the distributed matrix A .

work

On exit, $\text{work}(1)$ returns the minimal and optimal lwork .

info

(local).INTEGER.

If $\text{info} = 0$, the execution is successful.

If $\text{info} < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = - (i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

Application Notes

The matrix Q is represented as a product of $(ih:i-ilo)$ elementary reflectors

$$Q = H(i-ilo) * H(i-ilo+1) * \dots * H(ih-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{\text{au}} * v * v'$$

where τ_{au} is a real/complex scalar, and v is a real/complex vector with $v(1: i)=0$, $v(i+1)=1$ and $v(ih+1:n)=0$; $v(i+2:ih)$ is stored on exit in $A(ia+ilo+i:ia+ih-1, ia+ilo+i-2)$, and τ_{au} in $\tau_{\text{au}}(ja+ilo+i-2)$.

The contents of $A(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ih = 6$:

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ a & h & h & h & h & h & a \\ h & h & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ a & a & a & a & a & a & a \end{bmatrix}$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and vi denotes an element of the vector defining $H(ja+ilo+i-2)$.

p?gelq2

Computes an LQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgelq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C:\mkl_scalapack.h

Description

The `p?gelq2` routine computes an LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L^*Q$.

Input Parameters

<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<code>a</code>	(local). REAL for <code>psgelq2</code> DOUBLE PRECISION for <code>pdgelq2</code> COMPLEX for <code>pcgelq2</code> COMPLEX*16 for <code>pzgelq2</code> . Pointer into the local memory to an array of DIMENSION (<code>lld_a, LOCc(ja+n-1)</code>). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array <code>a</code> indicating the first row and the first column of the submatrix <code>A</code> , respectively.
<code>desca</code>	(global and local) INTEGER array, DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix <code>A</code> .
<code>work</code>	(local). REAL for <code>psgelq2</code> DOUBLE PRECISION for <code>pdgelq2</code> COMPLEX for <code>pcgelq2</code> COMPLEX*16 for <code>pzgelq2</code> . This is a workspace array of DIMENSION (<code>lwork</code>).
<code>lwork</code>	(local or global) INTEGER. The dimension of the array <code>work</code> . <code>lwork</code> is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$, where $iwoff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$, $mp0 = \text{numroc}(m+iwoff, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcol)$, <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <code>myrow</code> , <code>mycol</code> , <code>nprow</code> , and <code>npcol</code> can be determined by calling the subroutine <code>blacs_gridinfo</code> . If <code>lwork = -1</code> , then <code>lwork</code> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>pxerbla</code> .

Output Parameters

<code>a</code>	(local).
----------------	----------

On exit, the elements on and below the diagonal of $\text{sub}(A)$ contain the m by $\min(m, n)$ lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array τ_{au} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

 τ_{au}

(local).

REAL for psgelq2
 DOUBLE PRECISION for pdgelq2
 COMPLEX for pcgelq2
 COMPLEX*16 for pzgelq2.

Array, DIMENSION $\text{LOCr}(ia + \min(m, n) - 1)$. This array contains the scalar factors of the elementary reflectors. τ_{au} is tied to the distributed matrix A .

 $work$ On exit, $work(1)$ returns the minimal and optimal $lwork$. $info$

(local).INTEGER. If $info = 0$, the execution is successful. If $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia+k-1)^H * H(ia+k-2)^H * \dots * H(ia)^H \text{ for real flavors, } Q = (H(ia+k-1))^H * (H(ia+k-2))^H * \dots * (H(ia))^H \text{ for complex flavors,}$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau_{au}^* v^* v'$$

where τ_{au} is a real/complex scalar, and v is a real/complex vector with $v(1: i-1) = 0$ and $v(i) = 1$; $v(i+1: n)$ (for real flavors) or $\text{conjg}(v(i+1: n))$ (for complex flavors) is stored on exit in $A(ia+i-1, ja+i: ja+n-1)$, and τ_{au} in $TAU(ia+i-1)$.

p?geql2

Computes a QL factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeql2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?geql2 routine computes a QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$.

Input Parameters

m (global) INTEGER.
The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).

n (global) INTEGER.
The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).

a (local).
REAL for `psgeql2`
DOUBLE PRECISION for `pdgeql2`
COMPLEX for `pcgeql2`
COMPLEX*16 for `pzgeql2`.
Pointer into the local memory to an array of DIMENSION ($lld_a, LOCc(ja + n - 1)$).
On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.

ia, ja (global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix *A*, respectively.

desca (global and local) INTEGER array, DIMENSION (*dlen*). The array descriptor for the distributed matrix *A*.

work (local).
REAL for `psgeql2`
DOUBLE PRECISION for `pdgeql2`
COMPLEX for `pcgeql2`
COMPLEX*16 for `pzgeql2`.
This is a workspace array of DIMENSION (*lwork*).

lwork (local or global) INTEGER.
The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $iwoff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$, $mp0 = \text{numroc}(m+iwoff, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcol)$, `indxg2p` and `numroc` are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine `blacs_gridinfo`. If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a (local).
On exit,
if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix *L*;
if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix *L*; the remaining elements, with the array *tau*, represent the orthogonal/ unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

<i>tau</i>	(local). REAL for psgeql2 DOUBLE PRECISION for pdgeql2 COMPLEX for pcgeql2 COMPLEX*16 for pzgeql2. Array, DIMENSION $\text{LOCc}(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local). INTEGER. If <i>info</i> = 0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tauau * v * v'$$

where τau is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τau in $TAU(ja+n-k+i-1)$.

p?geqr2

Computes a QR factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgeqr2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C:\mkl_scalapack.h

Description

The p?geqr2 routine computes a QR factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * R$.

Input Parameters

<i>m</i>	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local).

REAL for psgeqr2
 DOUBLE PRECISION for pdgeqr2
 COMPLEX for pcgeqr2
 COMPLEX*16 for pzgeqr2.
 Pointer into the local memory to an array of DIMENSION (lld_a , $LOCc(ja + n - 1)$).
 On entry, this array contains the local pieces of the m -by- n distributed matrix sub(A) which is to be factored.

ia, ja
 (global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

desca
 (global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .

work
 (local).
 REAL for psgeqr2
 DOUBLE PRECISION for pdgeqr2
 COMPLEX for pcgeqr2
 COMPLEX*16 for pzgeqr2.
 This is a workspace array of DIMENSION ($lwork$).
lwork
 (local or global). INTEGER.
 The dimension of the array *work*.
lwork is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $iwoff = \text{mod}(ia-1, mb_a)$, $icoff = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$, $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$, $mp0 = \text{numroc}(m+iwoff, mb_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoff, nb_a, mycol, iacol, npcol)$.
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine *blacs_gridinfo*. If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a
 (local).
 On exit, the elements on and above the diagonal of sub(A) contain the $\min(m, n)$ by n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

tau
 (local).
 REAL for psgeqr2
 DOUBLE PRECISION for pdgeqr2
 COMPLEX for pcgeqr2
 COMPLEX*16 for pzgeqr2.
 Array, DIMENSION $LOCc(ja + \min(m, n) - 1)$. This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix A .

work
 On exit, *work*(1) returns the minimal and optimal *lwork*.

info
 (local). INTEGER.
 If *info* = 0, the execution is successful. If *info* < 0:

If the i -th argument is an array and the j -entry had an illegal value, then
 $info = - (i*100+j)$,
if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(j) = I - tau * v * v^T,$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and tau in $TAU(ja+i-1)$.

p?gerq2

Computes an RQ factorization of a general rectangular matrix (unblocked algorithm).

Syntax

```
call psgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pdgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pcgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
call pzgerq2(m, n, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?gerq2 routine computes an RQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R*Q$.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). REAL for psgerq2 DOUBLE PRECISION for pdgerq2 COMPLEX for pcgerq2 COMPLEX*16 for pzgerq2. Pointer into the local memory to an array of DIMENSION (lld_a, LOCc(ja + n - 1)). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
ia, ja	(global) INTEGER. The row and column indices in the global array a indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). REAL for <i>psgerq2</i> DOUBLE PRECISION for <i>pdgerq2</i> COMPLEX for <i>pcgerq2</i> COMPLEX*16 for <i>pzgerq2</i> . This is a workspace array of DIMENSION (<i>lwork</i>).
<i>lwork</i>	(local or global). INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$, where $\begin{aligned} iroff = \text{mod}(ia-1, mb_a), & \quad icoff = \text{mod}(ja-1, nb_a), \\ iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow), & \\ iacol = \text{indxg2p}(ja, nb_a, mycol, csr_a, npcol), & \quad mp0 = \\ \text{numroc}(m+iroff, mb_a, myrow, iarow, nprow), & \\ nq0 = \text{numroc}(n+icoft, nb_a, mycol, iacol, npcol), & \\ \text{indxg2p and numroc are ScaLAPACK tool functions; } & \quad myrow, mycol, nprow, \\ \text{and npcol can be determined by calling the subroutine blacs_gridinfo.} & \end{aligned}$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

Output Parameters

<i>a</i>	(local). On exit, if $m \leq n$, the upper triangle of $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix <i>R</i> ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix <i>R</i> ; the remaining elements, with the array <i>tau</i> , represent the orthogonal/ unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local). REAL for <i>psgerq2</i> DOUBLE PRECISION for <i>pdgerq2</i> COMPLEX for <i>pcgerq2</i> COMPLEX*16 for <i>pzgerq2</i> . Array, DIMENSION $LOCr(ia+m-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local). INTEGER. If <i>info</i> = 0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1) \text{ for real flavors,}$$

$Q = (H(ia))^H * (H(ia+1))^H \dots * (H(ia+k-1))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - tau * v * v'$,

where tau is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ for real flavors or $\text{conjg}(v(1:n-k+i-1))$ for complex flavors is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and tau in $TAU(ia+m-k+i-1)$.

p?getf2

Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).

Syntax

```
call psgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pdgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pcgetf2(m, n, a, ia, ja, desca, ipiv, info)
call pzgetf2(m, n, a, ia, ja, desca, ipiv, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?getf2 routine computes an LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using partial pivoting with row interchanges.

The factorization has the form $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Input Parameters

m	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
n	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($nb_a - \text{mod}(ja-1, nb_a) \geq n \geq 0$).
a	(local). REAL for psgetf2 DOUBLE PRECISION for pdgetf2 COMPLEX for pcgetf2 COMPLEX*16 for pzgetf2. Pointer into the local memory to an array of DIMENSION($l1d_a, LOc(ja+n-1)$). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>ipiv</i>	(local). INTEGER. Array, DIMENSION ($\text{LOCr}(m_a) + mb_a$). This array contains the pivoting information. $ipiv(i) \rightarrow$ The global row that local row <i>i</i> was swapped with. This array is tied to the distributed matrix <i>A</i> .
<i>info</i>	(local). INTEGER. If $info = 0$: successful exit. If $info < 0$: <ul style="list-style-type: none"> if the <i>i</i>-th argument is an array and the <i>j</i>-entry had an illegal value, then $info = -(i*100+j)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then $info = -i$. If $info > 0$: If $info = k$, $u(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor <i>u</i> is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?labrd

Reduces the first *nb* rows and columns of a general rectangular matrix *A* to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of *A*.

Syntax

```
call pslabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
call pdlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
call pclabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
call pzlabrd(m, n, nb, a, ia, ja, desca, d, e, tauq, taup, x, ix, jx, descx, y, iy, jy, descy, work)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?labrd` routine reduces the first *nb* rows and columns of a real/complex general *m*-by-*n* distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form by an orthogonal/unitary transformation $Q^* A P$, and returns the matrices *X* and *Y* necessary to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $m \geq n$, $\text{sub}(A)$ is reduced to upper bidiagonal form; if $m < n$, $\text{sub}(A)$ is reduced to lower bidiagonal form.

This is an auxiliary routine called by [p?gebrd](#).

Input Parameters

<i>m</i>	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>nb</i>	(global) INTEGER. The number of leading rows and columns of $\text{sub}(A)$ to be reduced.
<i>a</i>	(local). REAL for <code>pslabrd</code> DOUBLE PRECISION for <code>pdlabrd</code> COMPLEX for <code>pclabrd</code> COMPLEX*16 for <code>pzlabrd</code> . Pointer into the local memory to an array of DIMENSION(<i>lld_a</i> , <i>LOCc(ja+n-1)</i>). On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>a</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen</i>). The array descriptor for the distributed matrix A.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the global array <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array, DIMENSION (<i>dlen</i>). The array descriptor for the distributed matrix X.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the global array <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array, DIMENSION (<i>dlen</i>). The array descriptor for the distributed matrix Y.
<i>work</i>	(local). REAL for <code>pslabrd</code> DOUBLE PRECISION for <code>pdlabrd</code> COMPLEX for <code>pclabrd</code> COMPLEX*16 for <code>pzlabrd</code> Workspace array, DIMENSION (<i>lwork</i>) $lwork \geq nb_a + nq$, with $nq = \text{numroc}(n+\text{mod}(ia-1, nb_y), nb_y, mycol, iacol, npcol)$ $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$ <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the subroutine <code>blacs_gridinfo</code> .

Output Parameters

<i>a</i>	(local)
----------	---------

On exit, the first nb rows and columns of the matrix are overwritten; the rest of the distributed matrix $\text{sub}(A)$ is unchanged.

If $m \geq n$, elements on and below the diagonal in the first nb columns, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; and elements above the diagonal in the first nb rows, with the array τ_{ap} , represent the orthogonal/unitary matrix P as a product of elementary reflectors.

If $m < n$, elements below the diagonal in the first nb columns, with the array τ_{aq} , represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first nb rows, with the array τ_{ap} , represent the orthogonal/unitary matrix P as a product of elementary reflectors. See *Application Notes* below.

d

(local).

REAL for pslabrd
 DOUBLE PRECISION for pdlabrd
 COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd

Array, DIMENSION $\text{LOCr}(ia+\min(m,n)-1)$ if $m \geq n$; $\text{LOCc}(ja+\min(m,n)-1)$ otherwise. The distributed diagonal elements of the bidiagonal distributed matrix B :

$d(i) = A(ia+i-1, ja+i-1)$.

d is tied to the distributed matrix A .

e

(local).

REAL for pslabrd
 DOUBLE PRECISION for pdlabrd
 COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd

Array, DIMENSION $\text{LOCr}(ia+\min(m,n)-1)$ if $m \geq n$; $\text{LOCc}(ja+\min(m,n)-2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix B :

if $m \geq n$, $E(i) = A(ia+i-1, ja+i)$ for $i = 1, 2, \dots, n-1$;
 if $m < n$, $E(i) = A(ia+i, ja+i-1)$ for $i = 1, 2, \dots, m-1$.

e is tied to the distributed matrix A .

tauq, tauq

(local).

REAL for pslabrd
 DOUBLE PRECISION for pdlabrd
 COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd

Array DIMENSION $\text{LOCc}(ja+\min(m, n)-1)$ for τ_{aq} , DIMENSION $\text{LOCr}(ia+\min(m, n)-1)$ for τ_{ap} . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q for τ_{aq} , P for τ_{ap} . τ_{aq} and τ_{ap} are tied to the distributed matrix A . See *Application Notes* below.

x

(local)

REAL for pslabrd
 DOUBLE PRECISION for pdlabrd
 COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd

Pointer into the local memory to an array of DIMENSION (lld_x, nb). On exit, the local pieces of the distributed m -by- nb matrix $X(ix:ix+m-1, jx:jx+nb-1)$ required to update the unreduced part of $\text{sub}(A)$.

y

(local).

REAL for pslabrd
 DOUBLE PRECISION for pdlabrd
 COMPLEX for pclabrd
 COMPLEX*16 for pzlabrd
 Pointer into the local memory to an array of DIMENSION (*lld_y, nb*). On exit, the local pieces of the distributed *n*-by-*nb* matrix $Y(iy:iy+n-1, jy:jy+nb-1)$ required to update the unreduced part of $\text{sub}(A)$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb), \text{ and } P = G(1) * G(2) * \dots * G(nb)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{aq} v v^T, \text{ and } G(i) = I - \tau_{ap} u u^T,$$

where τ_{aq} and τ_{ap} are real/complex scalars, and v and u are real/complex vectors.

If $m \geq n$, $v(1: i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1); u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1); \tau_{aq}$ is stored in $TAUQ(ja+i-1)$ and τ_{ap} in $TAUP(ia+i-1)$.

If $m < n$, $v(1: i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1); u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1); \tau_{aq}$ is stored in $TAUQ(ja+i-1)$ and τ_{ap} in $TAUP(ia+i-1)$. The elements of the vectors v and u together form the m -by-*nb* matrix V and the *nb*-by-*n* matrix U' which are necessary, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $\text{sub}(A) := \text{sub}(A) - V^*Y' - X^*U'$. The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $nb = 2$:

$$\begin{array}{ll} m = 6 \text{ and } n = 5(m > n): & m = 5 \text{ and } n = 6(m < n): \\ \left[\begin{array}{cccc} 1 & 1 & v1 & v1 & v1 \\ v1 & 1 & 1 & u2 & u2 \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{array} \right] & \left[\begin{array}{cccccc} 1 & v1 & v1 & v1 & v1 & v1 \\ 1 & 1 & u2 & u2 & u2 & u2 \\ v1 & 1 & a & a & a & a \\ v1 & v2 & a & a & a & a \\ v1 & v2 & a & a & a & a \end{array} \right] \end{array}$$

where a denotes an element of the original matrix which is unchanged, vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

p?lacon

Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

```
call pslacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pdlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pclacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
call pzlacon(n, v, iv, jv, descv, x, ix, jx, descx, isgn, est, kase)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lacon` routine estimates the 1-norm of a square, real/unitary distributed matrix `A`. Reverse communication is used for evaluating matrix-vector products. `x` and `v` are aligned with the distributed matrix `A`, this information is implicitly contained within `iv`, `ix`, `descv`, and `descx`.

Input Parameters

<code>n</code>	(global). INTEGER. The length of the distributed vectors <code>v</code> and <code>x</code> . $n \geq 0$.
<code>v</code>	(local). REAL for <code>pslacon</code> DOUBLE PRECISION for <code>pdlacon</code> COMPLEX for <code>pclacon</code> COMPLEX*16 for <code>pzlacon</code> . Pointer into the local memory to an array of DIMENSION <code>LOCr(n+mod(iv-1, mb_v))</code> . On the final return, <code>v = a*w</code> , where <code>est = norm(v)/norm(w)</code> (<code>w</code> is not returned).
<code>iv, jv</code>	(global) INTEGER. The row and column indices in the global array <code>v</code> indicating the first row and the first column of the submatrix <code>V</code> , respectively.
<code>descv</code>	(global and local) INTEGER array, DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix <code>V</code> .
<code>x</code>	(local). REAL for <code>pslacon</code> DOUBLE PRECISION for <code>pdlacon</code> COMPLEX for <code>pclacon</code> COMPLEX*16 for <code>pzlacon</code> . Pointer into the local memory to an array of DIMENSION <code>LOCr(n+mod(ix-1, mb_x))</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the global array <code>x</code> indicating the first row and the first column of the submatrix <code>X</code> , respectively.
<code>descx</code>	(global and local) INTEGER array, DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix <code>X</code> .
<code>isgn</code>	(local). INTEGER. Array, DIMENSION <code>LOCr(n+mod(ix-1, mb_x))</code> . <code>isgn</code> is aligned with <code>x</code> and <code>v</code> .
<code>kase</code>	(local). INTEGER. On the initial call to <code>p?lacon</code> , <code>kase</code> should be 0.

Output Parameters

<code>x</code>	(local). On an intermediate return, <code>X</code> should be overwritten by A^*X , if <code>kase=1</code> , A^*X , if <code>kase=2</code> , <code>p?lacon</code> must be re-called with all the other parameters unchanged.
<code>est</code>	(global). REAL for single precision flavors DOUBLE PRECISION for double precision flavors
<code>kase</code>	(local) INTEGER. On an intermediate return, <code>kase</code> is 1 or 2, indicating whether <code>X</code> should be overwritten by A^*X , or $A^{**}X$. On the final return from <code>p?lacon</code> , <code>kase</code> is again 0.

p?laconsb

Looks for two consecutive small subdiagonal elements.

Syntax

```
call pslaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
```

```
call pdlaconsb(a, desca, i, l, m, h44, h33, h43h34, buf, lwork)
```

Include Files

- C: mkl_scalapack.h

Description

The p?laconsb routine looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift QR iteration given by $h44$, $h33$, and $h43h34$ to see if this process makes a subdiagonal negligible.

Input Parameters

<i>a</i>	(global). REAL for pslaconsb DOUBLE PRECISION for pdlaconsb Array, DIMENSION (desca (1ld_)*). On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER. Array of DIMENSION (dlen_). The array descriptor for the distributed matrix A.
<i>i</i>	(global) INTEGER. The global location of the bottom of the unreduced submatrix of A. Unchanged on exit.
<i>l</i>	(global) INTEGER. The global location of the top of the unreduced submatrix of A. Unchanged on exit.
<i>h44</i> , <i>h33</i> , <i>h43h34</i>	(global). REAL for pslaconsb DOUBLE PRECISION for pdlaconsb These three values are for the double shift QR iteration.
<i>lwork</i>	(global) INTEGER. This must be at least $7 * \text{ceil}(\text{ceil}((i-1)/hbl)/\text{lcm}(nprov, npcol))$. Here lcm is least common multiple and $nprov * npcol$ is the logical grid size.

Output Parameters

<i>m</i>	(global). On exit, this yields the starting location of the QR double shift. This will satisfy: $l \leq m \leq i-2$.
<i>buf</i>	(local). REAL for pslaconsb DOUBLE PRECISION for pdlaconsb Array of size <i>lwork</i> .
<i>lwork</i>	(global). On exit, <i>lwork</i> is the size of the work buffer.

p?lacp2

Copies all or part of a distributed matrix to another distributed matrix.

Syntax

```
call pslacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacp2(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- C:\mkl_scalapack.h

Description

The p?lacp2 routine copies all or part of a distributed matrix A to another distributed matrix B . No communication is performed, p?lacp2 performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, a:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

p?lacp2 requires that only dimension of the matrix operands is distributed.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied: = 'U': Upper triangular part is copied; the strictly lower triangular part of $\text{sub}(A)$ is not referenced; = 'L': Lower triangular part is copied; the strictly upper triangular part of $\text{sub}(A)$ is not referenced. Otherwise: all of the matrix $\text{sub}(A)$ is copied.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). REAL for pslacp2 DOUBLE PRECISION for pdlacp2 COMPLEX for pclacp2 COMPLEX*16 for pzlacp2. Pointer into the local memory to an array of DIMENSION (lld_a, LOCl(ja+n-1)). On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (dlen_). The array descriptor for the distributed matrix A.

<i>ib, jb</i>	(global) INTEGER. The row and column indices in the global array <i>B</i> indicating the first row and the first column of <i>sub(B)</i> , respectively.
<i>descb</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	(local). REAL for pslacp2 DOUBLE PRECISION for pdlacp2 COMPLEX for pclacp2 COMPLEX*16 for pzlacp2. Pointer into the local memory to an array of DIMENSION (<i>lld_b, LOCC(jb+n-1)</i>). This array contains on exit the local pieces of the distributed matrix <i>sub(B)</i> set as follows: if <i>uplo</i> = 'U', <i>B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 ≤ i ≤ j, 1 ≤ j ≤ n</i> ; if <i>uplo</i> = 'L', <i>B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), j ≤ i ≤ m, 1 ≤ j ≤ n</i> ; otherwise, <i>B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1), 1 ≤ i ≤ m, 1 ≤ j ≤ n</i> .
----------	--

p?lacp3

Copies from a global parallel array into a local replicated array or vice versa.

Syntax

```
call pslacp3(m, i, a, desca, b, ldb, ii, jj, rev)
call pdlacp3(m, i, a, desca, b, ldb, ii, jj, rev)
```

Include Files

- C: mkl_scalapack.h

Description

This is an auxiliary routine that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

Input Parameters

<i>m</i>	(global) INTEGER. <i>m</i> is the order of the square submatrix that is copied. <i>m</i> ≥ 0. Unchanged on exit.
<i>i</i>	(global) INTEGER. <i>A(i, i)</i> is the global location that the copying starts from. Unchanged on exit.
<i>a</i>	(global). REAL for pslacp3 DOUBLE PRECISION for pdlacp3 Array, DIMENSION (<i>desca(lld_),*</i>). On entry, the parallel matrix to be copied into or from.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

<i>b</i>	(local). REAL for pslacp3 DOUBLE PRECISION for pdlacp3 Array, DIMENSION (<i>ldb</i> , <i>m</i>). If <i>rev</i> = 0, this is the global portion of the array $A(i:i+m-1, i:i+m-1)$. If <i>rev</i> = 1, this is the unchanged on exit.
<i>ldb</i>	(local) INTEGER. The leading dimension of <i>B</i> .
<i>ii</i>	(global) INTEGER. By using <i>rev</i> 0 and 1, data can be sent out and returned again. If <i>rev</i> = 0, then <i>ii</i> is destination row index for the node(s) receiving the replicated <i>B</i> . If <i>ii</i> ≥ 0 , <i>jj</i> ≥ 0 , then node (<i>ii</i> , <i>jj</i>) receives the data. If <i>ii</i> = -1, <i>jj</i> ≥ 0 , then all rows in column <i>jj</i> receive the data. If <i>ii</i> ≥ 0 , <i>jj</i> = -1, then all cols in row <i>ii</i> receive the data. If <i>ii</i> = -1, <i>jj</i> = -1, then all nodes receive the data. If <i>rev</i> != 0, then <i>ii</i> is the source row index for the node(s) sending the replicated <i>B</i> .
<i>jj</i>	(global) INTEGER. Similar description as <i>ii</i> above.
<i>rev</i>	(global) INTEGER. Use <i>rev</i> = 0 to send global <i>A</i> into locally replicated <i>B</i> (on node (<i>ii</i> , <i>jj</i>)). Use <i>rev</i> != 0 to send locally replicated <i>B</i> from node (<i>ii</i> , <i>jj</i>) to its owner (which changes depending on its location in <i>A</i>) into the global <i>A</i> .

Output Parameters

<i>a</i>	(global). On exit, if <i>rev</i> = 1, the copied data. Unchanged on exit if <i>rev</i> = 0.
<i>b</i>	(local). If <i>rev</i> = 1, this is unchanged on exit.

p?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
call pslacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pdlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pclacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
call pzlacpy(uplo, m, n, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lacpy routine copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacpy performs a local copy $\text{sub}(B) := \text{sub}(A)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

Input Parameters

<i>uplo</i>	(global). CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied:
-------------	---

= 'U': Upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not referenced;
 = 'L': Lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
 Otherwise: all of the matrix $\text{sub}(A)$ is copied.

m

(global) INTEGER.

The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).*n*

(global) INTEGER.

The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).*a*

(local).

REAL for pslacpy

DOUBLE PRECISION for pdlacpy

COMPLEX for pclacpy

COMPLEX*16 for pzlacpy.

Pointer into the local memory to an array of DIMENSION (lld_a , $LOCc(ja + n - 1)$).On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$.*ia, ja*(global) INTEGER. The row and column indices in the global array *a* indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.*desca*(global and local) INTEGER array, DIMENSION (*dlen*). The array descriptor for the distributed matrix A.*ib, jb*(global) INTEGER. The row and column indices in the global array *B* indicating the first row and the first column of $\text{sub}(B)$ respectively.*descb*(global and local) INTEGER array, DIMENSION (*dlen*). The array descriptor for the distributed matrix B.

Output Parameters

b

(local).

REAL for pslacpy

DOUBLE PRECISION for pdlacpy

COMPLEX for pclacpy

COMPLEX*16 for pzlacpy.

Pointer into the local memory to an array of DIMENSION (lld_b , $LOCc(jb + n - 1)$). This array contains on exit the local pieces of the distributed matrix $\text{sub}(B)$ set as follows:if $uplo = 'U'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq j$, $1 \leq j \leq n$;if $uplo = 'L'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $j \leq i \leq m$, $1 \leq j \leq n$;otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq m$, $1 \leq j \leq n$.

p?laevswp

Moves the eigenvectors from where they are computed to ScalAPACK standard block cyclic array.

Syntax

```
call pslaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
```

```
call pdlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
```

```
call pclaevevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
call pzlaevswp(n, zin, ldzi, z, iz, jz, descz, nvs, key, rwork, lrwork)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?laevswp` routine moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

Input Parameters

`np` = the number of rows local to a given process.

`nq` = the number of columns local to a given process.

`n` (global). INTEGER.

The order of the matrix `A`. $n \geq 0$.

`zin` (local).

REAL for `pslaevswp`

DOUBLE PRECISION for `pdlaevswp`

COMPLEX for `pclaevevswp`

COMPLEX*16 for `pzlaevswp`. Array, DIMENSION (`ldzi, nvs(iam)`). The eigenvectors on input. Each eigenvector resides entirely in one process. Each process holds a contiguous set of `nvs(iam)` eigenvectors. The first eigenvector which the process holds is: sum for $i=[0, iam-1]$ of `nvs(i)`.

`ldzi` (local)

INTEGER. The leading dimension of the `zin` array.

`iz, jz`

(global) INTEGER. The row and column indices in the global array `Z` indicating the first row and the first column of the submatrix `Z`, respectively.

`descz`

(global and local) INTEGER array, DIMENSION (`dlen_`). The array descriptor for the distributed matrix `Z`.

`nvs`

(global) INTEGER.

Array, DIMENSION(`nprocs+1`)

`nvs(i)` = number of processes number of eigenvectors held by processes $[0, i-1]$

`nvs(1)` = number of eigen vectors held by $[0, 1 -1] = 0$

`nvs(nprocs+1)=` number of eigen vectors held by $[0, nprocs]=$ total number of eigenvectors.

`key`

(global) INTEGER.

Array, DIMENSION (`n`). Indicates the actual index (after sorting) for each of the eigenvectors.

`rwork`

(local).

REAL for `pslaevswp`

DOUBLE PRECISION for `pdlaevswp`

COMPLEX for `pclaevevswp`

COMPLEX*16 for `pzlaevswp`. Array, DIMENSION (`lrwork`).

`lrwork`

(local)

INTEGER. Dimension of `work`.

Output Parameters

`z` (local).

REAL **for** pslaevswp
 DOUBLE PRECISION **for** pdlaevswp
 COMPLEX **for** pclaevswp
 COMPLEX*16 **for** pzlaevswp.
 Array, global DIMENSION (n, n), local DIMENSION ($descz(dlen_)$, nq). The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of nb .

p?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k-th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.

Syntax

```
call pslahrd( $n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work$ )
call pdlahrd( $n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work$ )
call pclahrd( $n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work$ )
call pzlahrd( $n, k, nb, a, ia, ja, desca, tau, t, y, iy, jy, descy, work$ )
```

Include Files

- C: mkl_scalapack.h

Description

The p?lahrd routine reduces the first nb columns of a real general n -by- $(n-k+1)$ distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$ so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q^*A^*Q . The routine returns the matrices V and T which determine Q as a block reflector $I-V^*T^*V'$, and also the matrix $Y = A^*V^*T$.

This is an auxiliary routine called by p?gehrd. In the following comments sub(A) denotes $A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

n	(global) INTEGER. The order of the distributed submatrix sub(A). $n \geq 0$.
k	(global) INTEGER. The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
nb	(global) INTEGER. The number of columns to be reduced.
a	(local). REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Pointer into the local memory to an array of DIMENSION ($lld_a, LOCc(ja+n-k)$). On entry, this array contains the local pieces of the n -by- $(n-k+1)$ general distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>iY, jY</i>	(global) INTEGER. The row and column indices in the global array <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>Y</i> .
<i>work</i>	(local). REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Array, DIMENSION (<i>nb</i>).

Output Parameters

<i>a</i>	(local). On exit, the elements on and above the <i>k</i> -th subdiagonal in the first <i>nb</i> columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the <i>k</i> -th subdiagonal, with the array <i>tau</i> , represent the matrix <i>Q</i> as a product of elementary reflectors. The other columns of <i>A</i> (<i>ia</i> : <i>ia+n-1</i> , <i>ja</i> : <i>ja+n-k</i>) are unchanged. (See <i>Application Notes</i> below.)
<i>tau</i>	(local) REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Array, DIMENSION <i>LOCc(ja+n-2)</i> . The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>t</i>	(local) REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Array, DIMENSION (<i>nb_a</i> , <i>nb_a</i>) The upper triangular matrix <i>T</i> .
<i>y</i>	(local). REAL for pslahrd DOUBLE PRECISION for pdlahrd COMPLEX for pclahrd COMPLEX*16 for pzlahrd. Pointer into the local memory to an array of DIMENSION (<i>lld_y</i> , <i>nb_a</i>). On exit, this array contains the local pieces of the <i>n</i> -by- <i>nb</i> distributed matrix <i>Y</i> . $lld_y \geq LOCr(ia+n-1)$.

Application Notes

The matrix *Q* is represented as a product of *nb* elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb).$$

Each $H(i)$ has the form

$$H(i) = i - \tau v^* v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $A(ia+i+k:ia+n-1, ja+i-1)$, and τ in $TAU(ja+i-1)$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix v which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form: $A(ia:ia+n-1, ja:ja+n-k) := (I - V^* T^* V') * (A(ia:ia+n-1, ja:ja+n-k) - Y^* V')$. The contents of $A(ia:ia+n-1, ja:ja+n-k)$ on exit are illustrated by the following example with $n = 7$, $k = 3$, and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix $A(ia:ia+n-1, ja:ja+n-k)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(i)$.

p?laect

Exploits IEEE arithmetic to accelerate the computations of eigenvalues. (C interface function).

Syntax

```
void psblaect(float *sigma, int *n, float *d, int *count);
void pdblaectb(float *sigma, int *n, float *d, int *count);
void pdblaectl(float *sigma, int *n, float *d, int *count);
```

Include Files

- C: mkl_scalapack.h

Description

The p?laect routine computes the number of negative eigenvalues of $(A - \sigma I)$. This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real routine psblaect is assumed to be bit 32. Double precision routines pdblaectb and pdblaectl differ in the order of the double precision word storage and, consequently, in the signbit location. For pdblaectb, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For pdblaectl, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

<i>sigma</i>	Real for psblaect
--------------	-------------------

DOUBLE PRECISION for pdlaiectb/pdlaiectl.
 The shift. p?laiect finds the number of eigenvalues less than equal to σ .

n INTEGER. The order of the tridiagonal matrix T . $n \geq 1$.

d Real for pslaiect
 DOUBLE PRECISION for pdlaiectb/pdlaiectl.
 Array of DIMENSION($2n - 1$).
 On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix T . These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of T are in the entries $d(1), d(3), \dots, d(2n-1)$, while the squares of the off-diagonal entries are $d(2), d(4), \dots, d(2n-2)$. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

Output Parameters

n INTEGER. The count of the number of eigenvalues of T less than or equal to σ .

p?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

Syntax

```
val = pslange(norm, m, n, a, ia, ja, desca, work)
val = pdlange(norm, m, n, a, ia, ja, desca, work)
val = pclange(norm, m, n, a, ia, ja, desca, work)
val = pzlange(norm, m, n, a, ia, ja, desca, work)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lange routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

norm (global) CHARACTER. Specifies what value is returned by the routine:
 = 'M' or 'm': $val = \max(|A_{ij}|)$, largest absolute value of the matrix A , it's not a matrix norm.
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

<i>m</i>	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix sub(<i>A</i>). When <i>m</i> = 0, p?lange is set to zero. $m \geq 0$.
<i>n</i>	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix sub(<i>A</i>). When <i>n</i> = 0, p?lange is set to zero. $n \geq 0$.
<i>a</i>	(local). Real for pslange DOUBLE PRECISION for pdlange COMPLEX for pclange COMPLEX*16 for pzlane. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i> , <i>loc_c(ja)</i> + <i>n</i> - 1)) containing the local pieces of the distributed matrix sub(<i>A</i>).
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). Real for pslange DOUBLE PRECISION for pdlange COMPLEX for pclange COMPLEX*16 for pzlane. Array DIMENSION (<i>lwork</i>). <i>lwork</i> ≥ 0 if <i>norm</i> = 'M' or 'm' (not referenced), <i>nq0</i> if <i>norm</i> = '1', 'O' or 'o', <i>mp0</i> if <i>norm</i> = 'I' or 'i', 0 if <i>norm</i> = 'F', 'f', 'E' or 'e' (not referenced), where <i>iroffa</i> = mod(<i>ia</i> -1, <i>mb_a</i>), <i>icoffa</i> = mod(<i>ja</i> -1, <i>nb_a</i>), <i>iarow</i> = indxg2p(<i>ia</i> , <i>mb_a</i> , <i>myrow</i> , <i>rsrc_a</i> , <i>nproc</i>), <i>iacol</i> = indxg2p(<i>ja</i> , <i>nb_a</i> , <i>mycol</i> , <i>csrc_a</i> , <i>npcol</i>), <i>mp0</i> = numroc(<i>m+iroffa</i> , <i>mb_a</i> , <i>myrow</i> , <i>iarow</i> , <i>nproc</i>), <i>nq0</i> = numroc(<i>n+icoffa</i> , <i>nb_a</i> , <i>mycol</i> , <i>iacol</i> , <i>npcol</i>), indxg2p and numroc are ScaLAPACK tool routines; <i>myrow</i> , <i>mycol</i> , <i>nproc</i> , and <i>npcol</i> can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

<i>val</i>	The value returned by the routine.
------------	------------------------------------

p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Syntax

```
val = pslanhs(norm, n, a, ia, ja, desca, work)
val = pdlanhs(norm, n, a, ia, ja, desca, work)
```

```
val = pclanhs(norm, n, a, ia, ja, desca, work)
val = pzlanhs(norm, n, a, ia, ja, desca, work)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lanhs` routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	CHARACTER*1. Specifies the value to be returned by the routine: = 'M' or 'm': <i>val</i> = $\max(A_{ij})$, largest absolute value of the matrix <i>A</i> . = '1' or 'O' or 'o': <i>val</i> = $\text{norm1}(A)$, 1-norm of the matrix <i>A</i> (maximum column sum), = 'I' or 'i': <i>val</i> = $\text{normI}(A)$, infinity norm of the matrix <i>A</i> (maximum row sum), = 'F', 'f', 'E' or 'e': <i>val</i> = $\text{normF}(A)$, Frobenius norm of the matrix <i>A</i> (square root of sum of squares).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. When <i>n</i> = 0, <code>p?lanhs</code> is set to zero. <i>n</i> ≥ 0 .
<i>a</i>	(local). Real for <code>pslanhs</code> DOUBLE PRECISION for <code>pdlanhs</code> COMPLEX for <code>pclanhs</code> COMPLEX*16 for <code>pzlanhs</code> . Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOCl(ja+n-1))</code> containing the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). Real for <code>pslanhs</code> DOUBLE PRECISION for <code>pdlanhs</code> COMPLEX for <code>pclanhs</code> COMPLEX*16 for <code>pzlanhs</code> . Array, <code>DIMENSION(lwork)</code> . $lwork \geq 0$ if <i>norm</i> = 'M' or 'm' (not referenced), $nq0$ if <i>norm</i> = '1', 'O' or 'o', $mp0$ if <i>norm</i> = 'I' or 'i', 0 if <i>norm</i> = 'F', 'f', 'E' or 'e' (not referenced), where $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$, $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,

```

iacol = indxg2p( ja, nb_a, mycol, csrc_a, npcol ),
mp0 = numroc( m+iroffa, mb_a, myrow, iarow, nprow ),
nq0 = numroc( n+icooffa, nb_a, mycol, iacol, npcol ),
indxg2p and numroc are ScaLAPACK tool routines; myrow, imycol, nprow,
and npcol can be determined by calling the subroutine blacs_gridinfo.

```

Output Parameters

<code>val</code>	The value returned by the function.
------------------	-------------------------------------

p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

Syntax

```

val = pslansy(norm, uplo, n, a, ia, ja, desca, work)
val = pdlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclansy(norm, uplo, n, a, ia, ja, desca, work)
val = pzlansy(norm, uplo, n, a, ia, ja, desca, work)
val = pclanhe(norm, uplo, n, a, ia, ja, desca, work)
val = pzlanhe(norm, uplo, n, a, ia, ja, desca, work)

```

Include Files

- C: mkl_scalapack.h

Description

The `p?lansy` and `p?lanhe` routines return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<code>norm</code>	(global) CHARACTER. Specifies what value is returned by the routine: = 'M' or 'm': $val = \max(A_{ij})$, largest absolute value of the matrix A , it's not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<code>uplo</code>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper triangular part of $\text{sub}(A)$ is referenced, = 'L': Lower triangular part of $\text{sub}(A)$ is referenced.
<code>n</code>	(global) INTEGER.

The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, p?lansy is set to zero. $n \geq 0$.

a

(local).
 REAL for pslansy
 DOUBLE PRECISION for pdlnsy
 COMPLEX for pclansy , pclanhe
 COMPLEX*16 for pzlansy , pzlanhe .

Pointer into the local memory to an array of DIMENSION ($\text{lld}_a, \text{LOCc}(\text{ja} + n - 1)$) containing the local pieces of the distributed matrix $\text{sub}(A)$.

If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If $\text{uplo} = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca

(global and local) INTEGER array, DIMENSION (dlen_a). The array descriptor for the distributed matrix A .

work

(local).
 REAL for pslansy , pclansy , pclanhe
 DOUBLE PRECISION for pdlnsy , pzlansy , pzlanhe
 Array DIMENSION (lwork).
 $\text{lwork} \geq 0$ if $\text{norm} = 'M'$ or ' m ' (not referenced),
 $2 * nq0 + mp0 + ldw$ if $\text{norm} = '1'$, ' O ' or ' o ', ' I ' or ' i ',
 where ldw is given by:
 if ($\text{nprow} \neq \text{npcol}$) then
 $ldw = mb_a * \text{ceil}(\text{ceil}(np0, mb_a), (lcm / nprow))$
 else
 $ldw = 0$
 end if
 0 if $\text{norm} = 'F'$, ' f ', ' E ' or ' e ' (not referenced),
 where lcm is the least common multiple of nprow and npcol , $lcm = \text{ilcm}(\text{nprow}, \text{npcol})$ and $\text{ceil}(x, y)$ is a ScaLAPACK function that returns ceiling (x/y).
 $iroffa = \text{mod}(ia - 1, mb_a)$, $icoffa = \text{mod}(ja - 1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$,
 $mp0 = \text{numroc}(m + iroffa, mb_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n + icoffa, nb_a, mycol, iacol, npcol)$,
 ilcm , ceil , indxg2p , and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the subroutine blacs_gridinfo .

Output Parameters

val

The value returned by the routine.

p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

```
val = pslantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pdlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pclantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
val = pzlantr(norm, uplo, diag, m, n, a, ia, ja, desca, work)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lantr` routine returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

norm (global) CHARACTER. Specifies what value is returned by the routine:
 = 'M' or 'm': $val = \max(|A_{ij}|)$, largest absolute value of the matrix A , it's not a matrix norm.
 = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum),
 = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum),
 = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

uplo (global) CHARACTER.
 Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced.
 = 'U': Upper trapezoidal,
 = 'L': Lower trapezoidal.
 Note that $\text{sub}(A)$ is triangular instead of trapezoidal if $m = n$.

diag (global). CHARACTER.
 Specifies whether the distributed matrix $\text{sub}(A)$ has unit diagonal.
 = 'N': Non-unit diagonal.
 = 'U': Unit diagonal.

m (global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, `p?lantr` is set to zero. $m \geq 0$.

n (global) INTEGER.
 The number of columns to be operated on i.e the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, `p?lantr` is set to zero. $n \geq 0$.

a (local).
 Real for `pslantr`
 DOUBLE PRECISION for `pdlantr`

COMPLEX for pclantr
 COMPLEX*16 for pzlantr.
 Pointer into the local memory to an array of DIMENSION(*lld_a*, *LOCc(ja*
 $+n-1)$) containing the local pieces of the distributed matrix sub(*A*).
ia, ja
 (global) INTEGER.
 The row and column indices in the global array *a* indicating the first row and
 the first column of the submatrix sub(*A*), respectively.
desca
 (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor
 for the distributed matrix A.
work
 (local).
 Real for pslantr
 DOUBLE PRECISION for pdlantr
 COMPLEX for pclantr
 COMPLEX*16 for pzlantr.
 Array DIMENSION (*lwork*).
 $lwork \geq 0$ if *norm* = 'M' or 'm' (not referenced),
nq0 if *norm* = '1', 'O' or 'o',
mp0 if *norm* = 'I' or 'i',
0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
iroffa = mod(*ia*-1, *mb_a*), *icoffa* = mod(*ja*-1, *nb_a*),
iarow = indxg2p(*ia*, *mb_a*, *myrow*, *rsrc_a*, *nprov*),
iacol = indxg2p(*ja*, *nb_a*, *mycol*, *csra_a*, *npcol*),
mp0 = numroc(*m+iroffa*, *mb_a*, *myrow*, *iarow*, *nprov*),
nq0 = numroc(*n+icoffa*, *nb_a*, *mycol*, *iacol*, *npcol*),
 indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprov*,
 and *npcol* can be determined by calling the subroutine blacs_gridinfo.

Output Parameters

val The value returned by the routine.

p?lapiv

Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

Syntax

```
call pslapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,  

iwork)  

call pdlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,  

iwork)  

call pclapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,  

iwork)  

call pzlapiv(direc, rowcol, pivroc, m, n, a, ia, ja, desca, ipiv, ip, jp, descip,  

iwork)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lapiv` routine applies either P (permutation matrix indicated by `ipiv`) or $\text{inv}(P)$ to a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix A . This routine will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of $\text{sub}(A)$, pass `rowcol='C'` and `pivroc='C'`.

Input Parameters

<code>direc</code>	(global) CHARACTER*1. Specifies in which order the permutation is applied: = 'F' (Forward). Applies pivots forward from top of matrix. Computes $P * \text{sub}(A)$. = 'B' (Backward). Applies pivots backward from bottom of matrix. Computes $\text{inv}(P) * \text{sub}(A)$.
<code>rowcol</code>	(global) CHARACTER*1. Specifies if the rows or columns are to be permuted: = 'R' Rows will be permuted, = 'C' Columns will be permuted.
<code>pivroc</code>	(global) CHARACTER*1. Specifies whether <code>ipiv</code> is distributed over a process row or column: = 'R' <code>ipiv</code> is distributed over a process row, = 'C' <code>ipiv</code> is distributed over a process column.
<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. When $m = 0$, <code>p?lapiv</code> is set to zero. $m \geq 0$.
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. When $n = 0$, <code>p?lapiv</code> is set to zero. $n \geq 0$.
<code>a</code>	(local). Real for <code>pslapiv</code> DOUBLE PRECISION for <code>pdlapiv</code> COMPLEX for <code>pclapiv</code> COMPLEX*16 for <code>pzlapiv</code> . Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOCr(ja + n - 1))</code> containing the local pieces of the distributed matrix $\text{sub}(A)$.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix A .
<code>ipiv</code>	(local). INTEGER. Array, <code>DIMENSION(lipiv)</code> ; when <code>rowcol='R' or 'r'</code> : $lipiv \geq LOCr(ia+m-1) + mb_a$ if <code>pivroc='C' or 'c'</code> , $lipiv \geq LOCc(m + \text{mod}(jp-1, nb_p))$ if <code>pivroc='R' or 'r'</code> , and, when <code>rowcol='C' or 'c'</code> : $lipiv \geq LOCr(n + \text{mod}(ip-1, mb_p))$ if <code>pivroc='C' or 'c'</code> ,

$lipiv \geq LOCc(ja+n-1) + nb_a$ if $pivroc='R'$ or ' r '.

This array contains the pivoting information. $ipiv(i)$ is the global row (column), local row (column) i was swapped with. When $rowcol='R'$ or ' r ' and $pivroc='C'$ or ' c ', or $rowcol='C'$ or ' c ' and $pivroc='R'$ or ' r ', the last piece of this array of size mb_a (resp. nb_a) is used as workspace. In those cases, this array is tied to the distributed matrix A .

ip, jp

(global) INTEGER. The row and column indices in the global array P indicating the first row and the first column of the submatrix $\text{sub}(P)$, respectively.

$descip$

(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed vector $ipiv$.

$iwork$

(local). INTEGER.

Array, DIMENSION (ldw), where ldw is equal to the workspace necessary for transposition, and the storage of the transposed $ipiv$:

Let lcm be the least common multiple of $nprow$ and $npcol$.

```
If(  $rowcol.eq.'r'$  .and.  $pivroc.eq.'r'$  ) then
```

```
  If(  $nprow.eq. npcol$  ) then
```

```
     $ldw = LOCr( n\_p + mod(jp-1, nb\_p) ) + nb\_p$ 
```

```
    else
```

```
     $ldw = LOCr( n\_p + mod(jp-1, nb\_p) ) +$ 
```

```
     $nb\_p * ceil( ceil(LOCc(n\_p)/nb\_p) / (lcm/npcol) )$ 
```

```
    end if
```

```
  else if(  $rowcol.eq.'c'$  .and.  $pivroc.eq.'c'$  ) then
```

```
    if(  $nprow.eq.$ 
```

```
       $npcol$  ) then
```

```
       $ldw = LOCc( m\_p + mod(ip-1, mb\_p) ) + mb\_p$ 
```

```
      else
```

```
       $ldw = LOCc( m\_p + mod(ip-1, mb\_p) ) +$ 
```

```
       $mb\_p * ceil(ceil(LOCr(m\_p)/mb\_p) / (lcm/nprow) )$ 
```

```
      end if
```

```
    else
```

```
       $iwork$  is not referenced.
```

```
    end if.
```

Output Parameters

a

(local).

On exit, the local pieces of the permuted distributed submatrix.

p?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.

Syntax

```
call pslaqge( $m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed$ )
```

```
call pdlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pclaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
call pzlaqge(m, n, a, ia, ja, desca, r, c, rowcnd, colcnd, amax, equed)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?laqge` routine equilibrates a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using the row and scaling factors in the vectors `r` and `c` computed by `p?geequ`.

Input Parameters

<code>m</code>	(global). INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<code>n</code>	(global). INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<code>a</code>	(local). REAL for <code>pslaqge</code> DOUBLE PRECISION for <code>pdlaqge</code> COMPLEX for <code>pclaqge</code> COMPLEX*16 for <code>pzlaqge</code> . Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOCc(ja+n-1))</code> . On entry, this array contains the distributed matrix $\text{sub}(A)$.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array <code>A</code> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix <code>A</code> .
<code>r</code>	(local). REAL for <code>pslaqge</code> DOUBLE PRECISION for <code>pdlaqge</code> COMPLEX for <code>pclaqge</code> COMPLEX*16 for <code>pzlaqge</code> . Array, <code>DIMENSION LOCr(m_a)</code> . The row scale factors for $\text{sub}(A)$. <code>r</code> is aligned with the distributed matrix <code>A</code> , and replicated across every process column. <code>r</code> is tied to the distributed matrix <code>A</code> .
<code>c</code>	(local). REAL for <code>pslaqge</code> DOUBLE PRECISION for <code>pdlaqge</code> COMPLEX for <code>pclaqge</code> COMPLEX*16 for <code>pzlaqge</code> . Array, <code>DIMENSION LOCc(n_a)</code> . The row scale factors for $\text{sub}(A)$. <code>c</code> is aligned with the distributed matrix <code>A</code> , and replicated across every process column. <code>c</code> is tied to the distributed matrix <code>A</code> .
<code>rowcnd</code>	(local). REAL for <code>pslaqge</code>

DOUBLE PRECISION for pdlaqge
 COMPLEX for pclaqge
 COMPLEX*16 for pzlaqge.
 The global ratio of the smallest $r(i)$ to the largest $r(i)$, $ia \leq i \leq ia+m-1$.

colcnd
 (local).
 REAL for pslaqge
 DOUBLE PRECISION for pdlaqge
 COMPLEX for pclaqge
 COMPLEX*16 for pzlaqge.
 The global ratio of the smallest $c(i)$ to the largest $c(i)$, $ia \leq i \leq ia+n-1$.

amax
 (global). REAL for pslaqge
 DOUBLE PRECISION for pdlaqge
 COMPLEX for pclaqge
 COMPLEX*16 for pzlaqge.
 Absolute value of largest distributed submatrix entry.

Output Parameters

a
 (local).
 On exit, the equilibrated distributed matrix. See *equed* for the form of the equilibrated distributed submatrix.

equed
 (global) CHARACTER.
 Specifies the form of equilibration that was done.
 = 'N': No equilibration
 = 'R': Row equilibration, that is, $\text{sub}(A)$ has been pre-multiplied by $\text{diag}(r(ia:ia+m-1))$,
 = 'C': column equilibration, that is, $\text{sub}(A)$ has been post-multiplied by $\text{diag}(c(ja:ja+n-1))$,
 = 'B': Both row and column equilibration, that is, $\text{sub}(A)$ has been replaced by $\text{diag}(r(ia:ia+m-1)) * \text{sub}(A) * \text{diag}(c(ja:ja+n-1))$.

p?laqsy

Scales a symmetric/Hermitian matrix, using scaling factors computed by p?poequ.

Syntax

```
call pslaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pdlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pclaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
call pzlaqsy(uplo, n, a, ia, ja, desca, sr, sc, scond, amax, equed)
```

Include Files

- C: mkl_scalapack.h

Description

The p?laqsy routine equilibrates a symmetric distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the scaling factors in the vectors *sr* and *sc*. The scaling factors are computed by p?poequ.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part.
<i>n</i>	(global) INTEGER. The order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>a</i>	(local). REAL for <code>pslaqsy</code> DOUBLE PRECISION for <code>pdlaqsy</code> COMPLEX for <code>pclaqsy</code> COMPLEX*16 for <code>pzlaqsy</code> . Pointer into the local memory to an array of DIMENSION (lld_a , $LOCc(ja + n - 1)$). On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. On entry, the local pieces of the distributed symmetric matrix $\text{sub}(A)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>sr</i>	(local) REAL for <code>pslaqsy</code> DOUBLE PRECISION for <code>pdlaqsy</code> COMPLEX for <code>pclaqsy</code> COMPLEX*16 for <code>pzlaqsy</code> . Array, DIMENSION $LOCr(m_a)$. The scale factors for $A(ia:ia+m-1, ja:ja + n - 1)$. <i>sr</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>sr</i> is tied to the distributed matrix <i>A</i> .
<i>sc</i>	(local) REAL for <code>pslaqsy</code> DOUBLE PRECISION for <code>pdlaqsy</code> COMPLEX for <code>pclaqsy</code> COMPLEX*16 for <code>pzlaqsy</code> . Array, DIMENSION $LOCc(m_a)$. The scale factors for $A(ia:ia+m-1, ja:ja + n - 1)$. <i>sr</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>sr</i> is tied to the distributed matrix <i>A</i> .
<i>scond</i>	(global). REAL for <code>pslaqsy</code> DOUBLE PRECISION for <code>pdlaqsy</code> COMPLEX for <code>pclaqsy</code> COMPLEX*16 for <code>pzlaqsy</code> . Ratio of the smallest $sr(i)$ (respectively $sc(j)$) to the largest $sr(i)$ (respectively $sc(j)$), with $ia \leq i \leq ia+n-1$ and $ja \leq j \leq ja+n-1$.

amax (global).
 REAL for pslaqsy
 DOUBLE PRECISION for pdlaqsy
 COMPLEX for pcclaqsy
 COMPLEX*16 for pzlaqsy.
 Absolute value of largest distributed submatrix entry.

Output Parameters

a On exit,
 if *equed* = 'Y', the equilibrated matrix:
 $\text{diag}(\text{sr}(ia:ia+n-1)) * \text{sub}(A) * \text{diag}(\text{sc}(ja:ja+n-1)).$

equed (global) CHARACTER*1.
 Specifies whether or not equilibration was done.
 = 'N': No equilibration.
 = 'Y': Equilibration was done, that is, $\text{sub}(A)$ has been replaced by:
 $\text{diag}(\text{sr}(ia:ia+n-1)) * \text{sub}(A) * \text{diag}(\text{sc}(ja:ja+n-1)).$

p?lared1d

*Redistributes an array assuming that the input array, *bycol*, is distributed across rows and that all process columns contain the same copy of *bycol*.*

Syntax

```
call pslared1d(n, ia, ja, desc, bycol, byall, work, lwork)
call pdlared1d(n, ia, ja, desc, bycol, byall, work, lwork)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lared1d routine redistributes a 1D array. It assumes that the input array *bycol* is distributed across rows and that all process column contain the same copy of *bycol*. The output array *byall* is identical on all processes and contains the entire array.

Input Parameters

np = Number of local rows in *bycol()*

n (global). INTEGER.
 The number of elements to be redistributed. $n \geq 0$.

ia, ja (global) INTEGER. *ia, ja* must be equal to 1.

desc (global and local) INTEGER array, DIMENSION 9. A 2D array descriptor, which describes *bycol*.

bycol (local).
 REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pcclared1d
 COMPLEX*16 for pzclared1d.

Distributed block cyclic array global DIMENSION (n), local DIMENSION np .
 $bycol$ is distributed across the process rows. All process columns are assumed to contain the same value.

work

(local).

REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlated1d.

DIMENSION ($lwork$). Used to hold the buffers sent from one process to another.

lwork

(local)

INTEGER. The size of the *work* array. $lwork \geq \text{numroc}(n, \text{desc}(\text{nb}__), 0, 0, npcol)$.

Output Parameters

byall

(global). REAL for pslared1d
 DOUBLE PRECISION for pdlared1d
 COMPLEX for pclared1d
 COMPLEX*16 for pzlated1d.

Global DIMENSION (n), local DIMENSION (n). *byall* is exactly duplicated on all processes. It contains the same values as *bycol*, but it is replicated across all processes rather than being distributed.

p?lared2d

*Redistributes an array assuming that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*.*

Syntax

```
call pslared2d(n, ia, ja, desc, byrow, byall, work, lwork)
call pdlared2d(n, ia, ja, desc, byrow, byall, work, lwork)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lared2d routine redistributes a 1D array. It assumes that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*. The output array *byall* will be identical on all processes and will contain the entire array.

Input Parameters

np = Number of local rows in *byrow()*

n

(global) INTEGER.

The number of elements to be redistributed. $n \geq 0$.

ia, ja(global) INTEGER. *ia, ja* must be equal to 1.*desc*

(global and local) INTEGER array, DIMENSION (*dlen_*). A 2D array descriptor, which describes *byrow*.

byrow

(local).

REAL **for** pslared2d
 DOUBLE PRECISION **for** pdlared2d
 COMPLEX **for** pclared2d
 COMPLEX*16 **for** pzlated2d.
Distributed block cyclic array global DIMENSION (*n*), local DIMENSION *np*.
bycol is distributed across the process columns. All process rows are
assumed to contain the same value.

work
(local).
REAL **for** pslared2d
DOUBLE PRECISION **for** pdlared2d
COMPLEX **for** pclared2d
COMPLEX*16 **for** pzlated2d.
DIMENSION (*lwork*). Used to hold the buffers sent from one process to
another.

lwork
(local).INTEGER. The size of the *work* array. *lwork* $\geq \text{numroc}(n, desc(\text{nb}__), 0, 0, npcol)$.

Output Parameters

byall
(global). REAL **for** pslared2d
DOUBLE PRECISION **for** pdlared2d
COMPLEX **for** pclared2d
COMPLEX*16 **for** pzlated2d.
Global DIMENSION(*n*), local DIMENSION (*n*). *byall* is exactly duplicated on
all processes. It contains the same values as *bycol*, but it is replicated
across all processes rather than being distributed.

p?larf

Applies an elementary reflector to a general
rectangular matrix.

Syntax

```
call pslarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarf(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Include Files

- C:\mkl\scalapack.h

Description

The p?larf routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex *m*-by-*n* distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau u^* v^* v,$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global). CHARACTER. = 'L': form $Q^* \text{sub}(C)$, = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>v</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf. Pointer into the local memory to an array of DIMENSION (<i>lld_v,*</i>) containing the local pieces of the distributed vectors <i>v</i> representing the Householder transformation <i>Q</i> , <i>v(iv:iv+m-1, jv)</i> if <i>side</i> = 'L' and <i>incv</i> = 1, <i>v(iv, jv:jv+m-1)</i> if <i>side</i> = 'L' and <i>incv</i> = <i>m_v</i> , <i>v(iv:iv+n-1, jv)</i> if <i>side</i> = 'R' and <i>incv</i> = 1, <i>v(iv, jv:jv+n-1)</i> if <i>side</i> = 'R' and <i>incv</i> = <i>m_v</i> . The vector <i>v</i> is the representation of <i>Q</i> . <i>v</i> is not used if <i>tau</i> = 0.
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>V</i> .
<i>incv</i>	(global) INTEGER. The global increment for the elements of <i>v</i> . Only two values of <i>incv</i> are supported in this version, namely 1 and <i>m_v</i> . <i>incv</i> must not be zero.
<i>tau</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf. Array, DIMENSION <i>LOCc(jv)</i> if <i>incv</i> = 1, and <i>LOCr(iv)</i> otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>v</i> .
<i>c</i>	(local). REAL for pslarf DOUBLE PRECISION for pdlarf COMPLEX for pclarf COMPLEX*16 for pzlarf. Pointer into the local memory to an array of DIMENSION (<i>lld_c, LOCc(jc+n-1)</i>), containing the local pieces of $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC (global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *C*.

work (local).

```

REAL for pslarf
DOUBLE PRECISION for pdlarf
COMPLEX for pclarf
COMPLEX*16 for pzlarf.
Array, DIMENSION (lwork).
If incv = 1,
  if side = 'L',
    if ivcol = iccol,
      lwork ≥ nqc0
    else
      lwork ≥ mpc0 + max( 1, nqc0 )
    end if
  else if side = 'R' ,
    lwork ≥ nqc0 + max( max( 1, mpc0 ), numroc(numroc( n +
      icoffc, nb_v, 0, 0, npcol ), nb_v, 0, 0, lcmq ) )
  end if
  else if incv = m_v,
    if side = 'L',
      lwork ≥ mpc0 + max( max( 1, nqc0 ), numroc(
        numroc(m+iroffc, mb_v, 0, 0, nprow ), mb_v, 0, 0, lcmp ) )
    else if side = 'R',
      if ivrow = icrow,
        lwork ≥ mpc0
      else
        lwork ≥ nqc0 + max( 1, mpc0 )
      end if
    end if
  end if,
  where lcm is the least common multiple of nprow and npcol and lcm =
ilcm( nprow, npcol ), lcmp = lcm/nprow, lcmq = lcm/npcol,
iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1, nb_c ),
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nprow ),
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol ),
mpc0 = numroc( m+iroffc, mb_c, myrow, icrow, nprow ),
nqc0 = numroc( n+icoffc, nb_c, mycol, iccol, npcol ),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the subroutine
blacs_gridinfo.
```

Output Parameters

c (local).
On exit, *sub(C)* is overwritten by the $Q^* \text{sub}(C)$ if *side* = 'L', or $\text{sub}(C)^* Q$ if *side* = 'R'.

p?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```
call pslarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c, ic, jc,
descc, work)

call pdlarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c, ic, jc,
descc, work)

call pclarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c, ic, jc,
descc, work)

call pzlarfb(side, trans, direct, storev, m, n, k, v, iv, jv, descv, t, c, ic, jc,
descc, work)
```

Include Files

- C: mkl_scalapack.h

Description

The p?larfb routine applies a real/complex block reflector Q or its transpose Q^T /conjugate transpose Q^H to a real/complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Input Parameters

<i>side</i>	(global).CHARACTER. if <i>side</i> = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Left; if <i>side</i> = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Right.
<i>trans</i>	(global).CHARACTER. if <i>trans</i> = 'N': no transpose, apply Q ; for real flavors, if <i>trans</i> = 'T': transpose, apply Q^T for complex flavors, if <i>trans</i> = 'C': conjugate transpose, apply Q^H ;
<i>direct</i>	(global) CHARACTER. Indicates how Q is formed from a product of elementary reflectors. if <i>direct</i> = 'F': $Q = H(1)*H(2)*\dots*H(k)$ (Forward) if <i>direct</i> = 'B': $Q = H(k)*\dots*H(2)*H(1)$ (Backward)
<i>storev</i>	(global) CHARACTER. Indicates how the vectors that define the elementary reflectors are stored: if <i>storev</i> = 'C': Columnwise if <i>storev</i> = 'R': Rowwise.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<i>k</i>	(global) INTEGER. The order of the matrix T.
<i>v</i>	(local). REAL for pslarfb DOUBLE PRECISION for pdlarfb COMPLEX for pclarfb COMPLEX*16 for pzlarfb.

Pointer into the local memory to an array of DIMENSION
 $(lld_v, LOCc(jv+k-1))$ if $storev = 'C'$,
 $(lld_v, LOCc(jv+m-1))$ if $storev = 'R'$ and $side = 'L'$,
 $(lld_v, LOCc(jv+n-1))$ if $storev = 'R'$ and $side = 'R'$.
It contains the local pieces of the distributed vectors v representing the Householder transformation.
if $storev = 'C'$ and $side = 'L'$, $lld_v \geq \max(1, LOCr(iv+m-1))$;
if $storev = 'C'$ and $side = 'R'$, $lld_v \geq \max(1, LOCr(iv+n-1))$;
if $storev = 'R'$, $lld_v \geq LOCr(jv+k-1)$.

iv, jv
(global) INTEGER.
The row and column indices in the global array v indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.

$descv$
(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix v .

c
(local).
REAL for pslarfb
DOUBLE PRECISION for pdlarfb
COMPLEX for pclarfb
COMPLEX*16 for pzlarfb.
Pointer into the local memory to an array of DIMENSION ($lld_c, LOCc(jc+n-1)$), containing the local pieces of $\text{sub}(c)$.

ic, jc
(global) INTEGER. The row and column indices in the global array c indicating the first row and the first column of the submatrix $\text{sub}(c)$, respectively.

$descc$
(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix c .

$work$
(local).
REAL for pslarfb
DOUBLE PRECISION for pdlarfb
COMPLEX for pclarfb
COMPLEX*16 for pzlarfb.
Workspace array, DIMENSION ($lwork$).
If $storev = 'C'$,
if $side = 'L'$,
 $lwork \geq (nqc0 + mpc0) * k$
else if $side = 'R'$,
 $lwork \geq (nqc0 + \max(npv0 + \text{numroc}(\text{numroc}(n + icoffc, nb_v, 0, 0, npcol), nb_v, 0, 0, lcmq), mpc0)) * k$
end if
else if $storev = 'R'$,
if $side = 'L'$,
 $lwork \geq (mpc0 + \max(mqv0 + \text{numroc}(\text{numroc}(m + iroffc, mb_v, 0, 0, nprow), mb_v, 0, 0, lcmq), nqc0)) * k$
else if $side = 'R'$,
 $lwork \geq (mpc0 + nqc0) * k$
end if
end if,
where

```

lcmq = lcm / npcol with lcm = iclm( nrow, npcol ),
iroffv = mod( iv-1, mb_v ), icoffv = mod( jv-1, nb_v ),
ivrow = indxg2p( iv, mb_v, myrow, rsrc_v, nrow ),
ivcol = indxg2p( jv, nb_v, mycol, csrc_v, npcol ),
MqV0 = numroc( m+icoffv, nb_v, mycol, ivcol, npcol ),
NpV0 = numroc( n+iroffv, mb_v, myrow, ivrow, nrow ),
iroffc = mod( ic-1, mb_c ), icoffc = mod( jc-1, nb_c ),
icrow = indxg2p( ic, mb_c, myrow, rsrc_c, nrow ),
iccol = indxg2p( jc, nb_c, mycol, csrc_c, npcol ),
MpC0 = numroc( m+iroffc, mb_c, myrow, icrow, nrow ),
NpC0 = numroc( n+icoffc, mb_c, myrow, icrow, nrow ),
NqC0 = numroc( n+icoffc, nb_c, mycol, iccol, npcol ),
ilcm, indxg2p, and numroc are ScalAPACK tool functions; myrow, mycol,
nrow, and npcol can be determined by calling the subroutine
blacs_gridinfo.

```

Output Parameters

<i>t</i>	(local). REAL for pslarfb DOUBLE PRECISION for pdlarfb COMPLEX for pclarfb COMPLEX*16 for pzlarfb. Array, DIMENSION(mb_v, mb_v) if storev = 'R', and (nb_v, nb_v) if storev = 'C'. The triangular matrix <i>t</i> is the representation of the block reflector.
<i>c</i>	(local). On exit, sub(<i>C</i>) is overwritten by the $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q'$. Q' is transpose (conjugate transpose) of Q .

p?larfc

Applies the conjugate transpose of an elementary reflector to a general matrix.

Syntax

```

call pclarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarfc(side, m, n, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)

```

Include Files

- C: mkl_scalapack.h

Description

The p?larfc routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = i - \tau v^* v^T,$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global).CHARACTER. if <i>side</i> = 'L': form $Q^H \cdot \text{sub}(C)$; if <i>side</i> = 'R': form $\text{sub}(C) \cdot Q^H$.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<i>v</i>	(local). COMPLEX for <code>pclarfc</code> COMPLEX*16 for <code>pzlarfc</code> . Pointer into the local memory to an array of DIMENSION ($lld_v, *$) containing the local pieces of the distributed vectors <i>v</i> representing the Householder transformation Q , $v(iv:iv+m-1, jv)$ if <i>side</i> = 'L' and <i>incv</i> = 1, $v(iv, jv:jv+m-1)$ if <i>side</i> = 'L' and <i>incv</i> = <i>m_v</i> , $v(iv:iv+n-1, jv)$ if <i>side</i> = 'R' and <i>incv</i> = 1, $v(iv, jv:jv+n-1)$ if <i>side</i> = 'R' and <i>incv</i> = <i>m_v</i> . The vector <i>v</i> is the representation of Q . <i>v</i> is not used if <i>tau</i> = 0.
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix $\text{sub}(V)$, respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (<i>dlen</i>). The array descriptor for the distributed matrix <i>V</i> .
<i>incv</i>	(global) INTEGER. The global increment for the elements of <i>v</i> . Only two values of <i>incv</i> are supported in this version, namely 1 and <i>m_v</i> . <i>incv</i> must not be zero.
<i>tau</i>	(local). COMPLEX for <code>pclarfc</code> COMPLEX*16 for <code>pzlarfc</code> . Array, DIMENSION $LOC_c(jv)$ if <i>incv</i> = 1, and $LOC_r(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>V</i> .
<i>c</i>	(local). COMPLEX for <code>pclarfc</code> COMPLEX*16 for <code>pzlarfc</code> . Pointer into the local memory to an array of DIMENSION ($lld_c, LOC_c(jc + n - 1)$), containing the local pieces of $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the global array <i>c</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descC</i>	(global and local) INTEGER array, DIMENSION (<i>dlen</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local). COMPLEX for <code>pclarfc</code> COMPLEX*16 for <code>pzlarfc</code> .

```

    Workspace array, DIMENSION (lwork).
    If incv = 1,
        if side = 'L',

    ilcm, indxg2p, and numroc are ScalAPACK tool functions; myrow, mycol,
    nprow, and npcol can be determined by calling the subroutine
    blacs_gridinfo.

```

Output Parameters

c

(local).

On exit, sub(*c*) is overwritten by the $Q^H * \text{sub}(C)$ if side = 'L', or $\text{sub}(C) * Q^H$ if side = 'R'.

p?larfg

Generates an elementary reflector (*Householder matrix*).

Syntax

```

call pslarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pdlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
call pclarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)

```

```
call pzlarfg(n, alpha, iax, jax, x, ix, jx, descx, incx, tau)
```

Include Files

- C: mkl_scalapack.h

Description

The p?larfg routine generates a real/complex elementary reflector H of order n , such that

$$H^* \text{sub}(X) = H^* \begin{pmatrix} x(iax, jax) \\ x \end{pmatrix} = \begin{pmatrix} alpha \\ 0 \end{pmatrix}, H'^* H = I,$$

where α is a scalar (a real scalar - for complex flavors), and $\text{sub}(x)$ is an $(n-1)$ -element real/complex distributed vector $X(ix:ix+n-2, jx)$ if $incx = 1$ and $X(ix, jx:jx+n-2)$ if $incx = descx(m_)$. H is represented in the form

$$H = I - tau * \begin{pmatrix} 1 \\ v \end{pmatrix} * (1 v')$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that H is not Hermitian.

If the elements of $\text{sub}(x)$ are all zero (and $X(iax, jax)$ is real for complex flavors), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise $1 \leq \text{real}(\tau) \leq 2$ and $\text{abs}(\tau-1) \leq 1$.

Input Parameters

n	(global) INTEGER. The global order of the elementary reflector. $n \geq 0$.
iax, jax	(global) INTEGER. The global row and column indices in x of $X(iax, jax)$.
x	(local). Real for pslarfg DOUBLE PRECISION for pdlarfg COMPLEX for pclarfg COMPLEX*16 for pzlarfg. Pointer into the local memory to an array of DIMENSION ($lld_x, *$). This array contains the local pieces of the distributed vector $\text{sub}(x)$. Before entry, the incremented array $\text{sub}(x)$ must contain vector x .
ix, jx	(global) INTEGER. The row and column indices in the global array x indicating the first row and the first column of $\text{sub}(x)$, respectively.
$descx$	(global and local) INTEGER. Array of DIMENSION ($dlen_$). The array descriptor for the distributed matrix x .
$incx$	(global) INTEGER. The global increment for the elements of x . Only two values of $incx$ are supported in this version, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

<i>alpha</i>	(local) REAL for pslafg DOUBLE PRECISION for pdlafg COMPLEX for pclafg COMPLEX*16 for pzlafg. On exit, <i>alpha</i> is computed in the process scope having the vector sub(<i>x</i>).
<i>x</i>	(local). On exit, it is overwritten with the vector <i>v</i> .
<i>tau</i>	(local). Real for psclarfg DOUBLE PRECISION for pdclarfg COMPLEX for pclarfg COMPLEX*16 for pzclarfg. Array, DIMENSION <i>LOCc(jx)</i> if <i>incx</i> = 1, and <i>LOCr(ix)</i> otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>x</i> .

p?larft

Forms the triangular vector *T* of a block reflector $H = I - V^* T^* V^H$.

Syntax

```
call psclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzclarft(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Include Files

- C: mkl_scalapack.h

Description

The p?larft routine forms the triangular factor *T* of a real/complex block reflector *H* of order *n*, which is defined as a product of *k* elementary reflectors.

If *direct* = 'F', $H = H(1)*H(2) \dots *H(k)$, and *T* is upper triangular;

If *direct* = 'B', $H = H(k)*\dots*H(2)*H(1)$, and *T* is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th column of the distributed matrix *V*, and

$$H = I - V^* T^* V^H$$

If *storev* = 'R', the vector which defines the elementary reflector $H(i)$ is stored in the *i*-th row of the distributed matrix *V*, and

$$H = I - V^* T^* V$$

Input Parameters

<i>direct</i>	(global) CHARACTER*1.
---------------	-----------------------

	Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if <i>direct</i> = 'F': $H = H(1)*H(2)*\dots*H(k)$ (forward) if <i>direct</i> = 'B': $H = H(k)*\dots*H(2)*H(1)$ (backward).
<i>storev</i>	(global) CHARACTER*1. Specifies how the vectors that define the elementary reflectors are stored (See Application Notes below): if <i>storev</i> = 'C': columnwise; if <i>storev</i> = 'R': rowwise.
<i>n</i>	(global) INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	(global) INTEGER. The order of the triangular factor T , is equal to the number of elementary reflectors. $1 \leq k \leq mb_v$ ($= nb_v$).
<i>v</i>	REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Pointer into the local memory to an array of local DIMENSION ($LOCr(iv+n-1), LOCc(jv+k-1)$) if <i>storev</i> = 'C', and ($LOCr(iv+k-1), LOCc(jv+n-1)$) if <i>storev</i> = 'R'. The distributed matrix <i>v</i> contains the Householder vectors. (See Application Notes below).
<i>iv, jv</i>	(global) INTEGER. The row and column indices in the global array <i>v</i> indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
<i>descv</i>	(global and local) INTEGER array, DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>v</i> .
<i>tau</i>	(local) REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Array, DIMENSION $LOCr(iv+k-1)$ if <i>incv</i> = m_v , and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix <i>v</i> .
<i>work</i>	(local). REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft. Workspace array, DIMENSION $(k*(k-1)/2)$.

Output Parameters

<i>v</i>	REAL for pslarft DOUBLE PRECISION for pdlarft COMPLEX for pclarft COMPLEX*16 for pzlarft.
----------	--

t (local)
 REAL for pslarft
 DOUBLE PRECISION for pdlarft
 COMPLEX for pclarft
 COMPLEX*16 for pzlarft.
 Array, DIMENSION (*nb_v*,*nb_v*) if *storev* = 'C', and (*mb_v*,*mb_v*) otherwise. It contains the *k*-by-*k* triangular factor of the block reflector associated with *v*. If *direct* = 'F', *t* is upper triangular; if *direct* = 'B', *t* is lower triangular.

Application Notes

The shape of the matrix *V* and the storage of the vectors that define the $H(i)$ is best illustrated by the following example with *n* = 5 and *k* = 3. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

$$\begin{array}{ll}
 \text{direct} = 'F' \text{ and } \text{storev} = 'C': & \text{direct} = 'F' \text{ and } \text{storev} = 'R' \\
 V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} 1 & & & & \\ v1 & 1 & & & \\ v1 & v2 & 1 & & \\ v1 & v2 & v3 & & \\ v1 & v2 & v3 & & \end{bmatrix} & V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} 1 & v1 & v1 & v1 & v1 \\ & 1 & v2 & v2 & v2 \\ & & 1 & v3 & v3 \end{bmatrix} \\
 \\
 \text{direct} = 'B' \text{ and } \text{storev} = 'C': & \text{direct} = 'B' \text{ and } \text{storev} = 'R' \\
 V(iv : iv + n - 1, \\ jv : jv + k - 1) = \begin{bmatrix} v1 & v2v & v3 \\ v1 & v2 & v3 \\ 1 & v2 & v3 \\ & 1 & v3 \\ & & 1 \end{bmatrix} & V(iv : iv + k - 1, \\ jv : jv + n - 1) = \begin{bmatrix} v1 & v1 & 1 \\ v2 & v2 & v2 & 1 \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix}
 \end{array}$$

p?larz

Applies an elementary reflector as returned by p?tzrzf to a general matrix.

Syntax

```

call pslarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pdlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pclarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarz(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)

```

Include Files

- C:\mkl_scalapack.h

Description

The `p?larz` routine applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v^* v,$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by `p?tzrzf`.

Input Parameters

<code>side</code>	(global) CHARACTER. if <code>side</code> = 'L': form $Q^* \text{sub}(C)$, if <code>side</code> = 'R': form $\text{sub}(C)^* Q$, $Q = Q^T$ (for real flavors).
<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).
<code>l</code>	(global). INTEGER. The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <code>side</code> = 'L', $m \geq l \geq 0$, if <code>side</code> = 'R', $n \geq l \geq 0$.
<code>v</code>	(local). REAL for <code>pslarz</code> DOUBLE PRECISION for <code>pdlarz</code> COMPLEX for <code>pclatz</code> COMPLEX*16 for <code>pzlatz</code> . Pointer into the local memory to an array of DIMENSION (<code>lld_v,*</code>) containing the local pieces of the distributed vectors v representing the Householder transformation Q , $v(iv:iv+l-1, jv)$ if <code>side</code> = 'L' and <code>incv</code> = 1, $v(iv, jv:jv+l-1)$ if <code>side</code> = 'L' and <code>incv</code> = m_v , $v(iv:iv+l-1, jv)$ if <code>side</code> = 'R' and <code>incv</code> = 1, $v(iv, jv:jv+l-1)$ if <code>side</code> = 'R' and <code>incv</code> = m_v . The vector v in the representation of Q . v is not used if $\tau = 0$.
<code>iv, jv</code>	(global) INTEGER. The row and column indices in the global array v indicating the first row and the first column of the submatrix $\text{sub}(v)$, respectively.
<code>descv</code>	(global and local) INTEGER array, DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix v .
<code>incv</code>	(global) INTEGER. The global increment for the elements of v . Only two values of <code>incv</code> are supported in this version, namely 1 and m_v . <code>incv</code> must not be zero.
<code>tau</code>	(local) REAL for <code>pslarz</code> DOUBLE PRECISION for <code>pdlarz</code>

COMPLEX for `pclarz`
 COMPLEX*16 for `pzlarz`.
 Array, DIMENSION $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. τ_a is tied to the distributed matrix V .

c
 (local).
 REAL for `pslarz`
 DOUBLE PRECISION for `pdlarz`
 COMPLEX for `pclarz`
 COMPLEX*16 for `pzlarz`.
 Pointer into the local memory to an array of DIMENSION (lld_c , $LOCc(jc + n - 1)$), containing the local pieces of $\text{sub}(C)$.

ic, jc
 (global) INTEGER.
 The row and column indices in the global array C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC
 (global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix C .

work
 (local).
 REAL for `pslarz`
 DOUBLE PRECISION for `pdlarz`
 COMPLEX for `pclarz`
 COMPLEX*16 for `pzlarz`.
 Array, DIMENSION ($lwork$)
 If $incv = 1$,
 if $side = 'L'$,
 if $ivcol = iccol$,
 $lwork \geq NqC0$
 else
 $lwork \geq MpC0 + \max(1, NqC0)$
 end if
 else if $side = 'R'$,
 $lwork \geq NqC0 + \max(\max(1, MpC0), \text{numroc}(\text{numroc}(n + iofffc, nb_v, 0, 0, npcol), nb_v, 0, 0, lcmq))$
 end if
 else if $incv = m_v$,
 if $side = 'L'$,
 $lwork \geq MpC0 + \max(\max(1, NqC0), \text{numroc}(\text{numroc}(m + iroffc, mb_v, 0, 0, nprow), mb_v, 0, 0, lcm))$
 else if $side = 'R'$,
 if $ivrow = icrow$,
 $lwork \geq MpC0$
 else
 $lwork \geq NqC0 + \max(1, MpC0)$
 end if
 end if
 end if.

Here lcm is the least common multiple of $nprow$ and $npcol$ and
 $lcm = \text{ilcm}(nprow, npcol)$, $lcm = lcm / nprow$,
 $lcmq = lcm / npcol$,
 $iroffc = \text{mod}(ic - 1, mb_c)$, $icofffc = \text{mod}(jc - 1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$,

*iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
 mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
 nqc0 = numroc(n+icooffc, nb_c, mycol, iccol, npcol),
 ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
 nprow, and npcol can be determined by calling the subroutine
 blacs_gridinfo.*

Output Parameters

c (local).
 On exit, $\text{sub}(C)$ is overwritten by the $Q^* \text{sub}(C)$ if $\text{side} = 'L'$, or
 $\text{sub}(C) * Q$ if $\text{side} = 'R'$.

p?larzb

Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.

Syntax

```
call pslarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)
call pdlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)
call pclarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)
call pzlarzb(side, trans, direct, storev, m, n, k, l, v, iv, jv, descv, t, c, ic, jc, descc, work)
```

Include Files

- C: mkl_scalapack.h

Description

The p?larzb routine applies a real/complex block reflector Q or its transpose Q^T (conjugate transpose Q^H for complex flavors) to a real/complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Q is a product of k elementary reflectors as returned by p?tzrzf.

Currently, only $\text{storev} = 'R'$ and $\text{direct} = 'B'$ are supported.

Input Parameters

<i>side</i>	(global) CHARACTER. if $\text{side} = 'L'$: apply Q or Q^T (Q^H for complex flavors) from the Left; if $\text{side} = 'R'$: apply Q or Q^T (Q^H for complex flavors) from the Right.
<i>trans</i>	(global) CHARACTER. if $\text{trans} = 'N'$: No transpose, apply Q ; If $\text{trans} = 'T'$: Transpose, apply Q^T (real flavors); If $\text{trans} = 'C'$: Conjugate transpose, apply Q^H (complex flavors).
<i>direct</i>	(global) CHARACTER. Indicates how H is formed from a product of elementary reflectors.

```

    if direct = 'F': H = H(1)*H(2)*...*H(k) - forward (not supported) ;
    if direct = 'B': H = H(k)*...*H(2)*H(1) - backward.

storev
(global) CHARACTER.
Indicates how the vectors that define the elementary reflectors are stored:
if storev = 'C': columnwise (not supported).
if storev = 'R': rowwise.

m
(global) INTEGER.
The number of rows to be operated on, that is, the number of rows of the
distributed submatrix sub(C). (m ≥ 0).

n
(global) INTEGER.
The number of columns to be operated on, that is, the number of columns
of the distributed submatrix sub(C). (n ≥ 0).

k
(global) INTEGER.
The order of the matrix T. (= the number of elementary reflectors whose
product defines the block reflector).

l
(global) INTEGER.
The columns of the distributed submatrix sub(A) containing the meaningful
part of the Householder reflectors.

If side = 'L', m ≥ l ≥ 0,
if side = 'R', n ≥ l ≥ 0.

v
(local).
REAL for pslarzb
DOUBLE PRECISION for pdlarzb
COMPLEX for pclarzb
COMPLEX*16 for pzlarzb.
Pointer into the local memory to an array of DIMENSION(lld_v, LOCc(jv
+m-1)) if side = 'L', (lld_v, LOCc(jv+m-1)) if side = 'R'.
It contains the local pieces of the distributed vectors v representing the
Householder transformation as returned by p?tzrzf.

lld_v ≥ LOCr(iv+k-1).

iv, jv
(global) INTEGER.
The row and column indices in the global array v indicating the first row and
the first column of the submatrix sub(V), respectively.

descv
(global and local) INTEGER array, DIMENSION (dlen_). The array descriptor
for the distributed matrix V.

t
(local)
REAL for pslarzb
DOUBLE PRECISION for pdlarzb
COMPLEX for pclarzb
COMPLEX*16 for pzlarzb.
Array, DIMENSION mb_v by mb_v.
The lower triangular matrix T in the representation of the block reflector.

c
(local).
REAL for pslarfb
DOUBLE PRECISION for pdlarfb
COMPLEX for pclarfb
COMPLEX*16 for pzlarfb.
Pointer into the local memory to an array of DIMENSION(lld_c, LOCc(jc
+n-1)).
```

On entry, the m -by- n distributed matrix $\text{sub}(c)$.

ic, jc

(global) INTEGER.

The row and column indices in the global array c indicating the first row and the first column of the submatrix $\text{sub}(c)$, respectively.

descC

(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix C .

work

(local).

REAL for pslarzb

DOUBLE PRECISION for pdlarzb

COMPLEX for pclarzb

COMPLEX*16 for pzlarzb .

Array, DIMENSION ($lwork$).

```
If storev = 'C' ,
```

```
  if side = 'L' ,
```

```
    lwork ≥ (nqc0 + mpc0) * k
```

```
  else if side = 'R' ,
```

```
    lwork ≥ (nqc0 + max(npv0 + numroc(numroc(n+icoffc, nb_v, 0, 0,
      npc0),
```

```
      nb_v, 0, 0, lcmq), mpc0)) * k
```

```
  end if
```

```
  else if storev = 'R' ,
```

```
    if side = 'L' ,
```

```
      lwork ≥ (mpc0 + max(mqv0 + numroc(numroc(m+iroffc, mb_v, 0, 0,
        nprow),
```

```
      mb_v, 0, 0, lcmq), nqc0)) * k
```

```
    else if side = 'R' ,
```

```
      lwork ≥ (mpc0 + nqc0) * k
```

```
    end if
```

```
  end if.
```

Here $lcmq = lcm/npc0$ with $lcm = \text{iclm}(nprow, npc0)$, $iroffv = \text{mod}(iv-1, mb_v)$, $icoffv = \text{mod}(jv-1, nb_v)$, $ivrow = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprow)$, $ivcol = \text{indxg2p}(jv, nb_v, mycol, csrc_v, ncol)$, $mqv0 = \text{numroc}(m+icoffv, nb_v, mycol, ivcol, ncol)$, $npv0 = \text{numroc}(n+iroffv, mb_v, myrow, ivrow, nprow)$, $iroffc = \text{mod}(ic-1, mb_c)$, $icoffc = \text{mod}(jc-1, nb_c)$, $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$, $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, ncol)$, $mpc0 = \text{numroc}(m+iroffc, mb_c, myrow, icrow, nprow)$, $npc0 = \text{numroc}(n+icoffc, mb_c, myrow, icrow, nprow)$, $nqc0 = \text{numroc}(n+icoffc, nb_c, mycol, iccol, ncol)$, $ilcm, \text{indxg2p}$, and numroc are ScaLAPACK tool functions; $myrow, mycol, nprow$, and $ncol$ can be determined by calling the subroutine blacs_gridinfo .

Output Parameters

c (local).
 On exit, $\text{sub}(C)$ is overwritten by the $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q'$, where Q' is the transpose (conjugate transpose) of Q .

p?larzc

Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.

Syntax

```
call pclarzc(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
call pzlarzc(side, m, n, l, v, iv, jv, descv, incv, tau, c, ic, jc, descc, work)
```

Include Files

- C: mkl_scalapack.h

Description

The p?larzc routine applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form $Q = i - \tau \cdot v^* v^T$,

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by p?tzrzf.

Input Parameters

side (global) CHARACTER.
 if *side* = 'L': form $Q^H * \text{sub}(C)$;
 if *side* = 'R': form $\text{sub}(C) * Q^H$.

m (global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. ($m \geq 0$).

n (global) INTEGER.
 The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. ($n \geq 0$).

l (global) INTEGER.
 The columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors.
 If *side* = 'L', $m \geq l \geq 0$,
 if *side* = 'R', $n \geq l \geq 0$.

v (local).
 COMPLEX for pclarzc
 COMPLEX*16 for pzlarzc.

Pointer into the local memory to an array of `DIMENSION (lld_v,*)` containing the local pieces of the distributed vectors `v` representing the Householder transformation Q ,

```
v(iv:iv+l-1, jv) if side = 'L' and incv = 1,
v(iv, jv:jv+l-1) if side = 'L' and incv = m_v,
v(iv:iv+l-1, jv) if side = 'R' and incv = 1,
v(iv, jv:jv+l-1) if side = 'R' and incv = m_v.
```

The vector `v` in the representation of Q . `v` is not used if `tau = 0`.

`iv, jv`

(global) INTEGER.

The row and column indices in the global array `v` indicating the first row and the first column of the submatrix `sub(v)`, respectively.

`descv`

(global and local) INTEGER array, `DIMENSION (dlen_)`. The array descriptor for the distributed matrix `v`.

`incv`

(global). INTEGER.

The global increment for the elements of `v`. Only two values of `incv` are supported in this version, namely 1 and `m_v`.
`incv` must not be zero.

`tau`

(local)

COMPLEX for `pclarzc`
 COMPLEX*16 for `pzlarzc`.

Array, `DIMENSION LOCc(jv)` if `incv = 1`, and `LOCr(iv)` otherwise. This array contains the Householder scalars related to the Householder vectors.
`tau` is tied to the distributed matrix `v`.

`c`

(local).

COMPLEX for `pclarzc`
 COMPLEX*16 for `pzlarzc`.

Pointer into the local memory to an array of `DIMENSION (lld_c, LOCc(jc +n-1))`, containing the local pieces of `sub(c)`.

`ic, jc`

(global) INTEGER.

The row and column indices in the global array `c` indicating the first row and the first column of the submatrix `sub(c)`, respectively.

`descc`

(global and local) INTEGER array, `DIMENSION (dlen_)`. The array descriptor for the distributed matrix `c`.

work

```
(local).

If incv = 1,
    if side = 'L' ,
        if ivcol = iccol,
            lwork ≥ nqc0
        else
            lwork ≥ mpc0 + max(1, nqc0)
        end if
    else if side = 'R' ,
        lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n+icoffc, nb_v, 0, 0,
npcol),
nb_v, 0, 0, lcmq))
    end if
else if incv = m_v,
    if side = 'L' ,
        lwork ≥ mpc0 + max(max(1, nqc0), numroc(numroc(m+iroffc, mb_v, 0, 0,
nprow),
mb_v, 0, 0, lcmq))
    else if side = 'R',
        if ivrow = icrow,
            lwork ≥ mpc0
        else
            lwork ≥ nqc0 + max(1, mpc0)
        end if
    end if
end if
```

Here lcm is the least common multiple of $nprow$ and $npcol$;
 $\text{lcm} = \text{ilcm}(nprow, npcol)$, $\text{lcm} = \text{lcm}/nprow$, $\text{lcm} = \text{lcm}/npcol$,
 $\text{iroffc} = \text{mod}(ic-1, mb_c)$, $\text{icoffc} = \text{mod}(jc-1, nb_c)$,
 $\text{icrow} = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$,
 $\text{iccol} = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol)$,
 $\text{mpc0} = \text{numroc}(m+iroffc, mb_c, myrow, icrow, nprow)$,
 $\text{nqc0} = \text{numroc}(n+icoffc, nb_c, mycol, iccol, npcol)$,
 ilcm , indxg2p , and numroc are ScalAPACK tool functions;
 myrow , mycol , nprow , and npcol can be determined by calling the
subroutine `blacs_gridinfo`.

Output Parameters

c

(local).

On exit, $\text{sub}(C)$ is overwritten by the $Q^H * \text{sub}(C)$ if $\text{side} = 'L'$, or
 $\text{sub}(C) * Q^H$ if $\text{side} = 'R'$.

p?larzt

Forms the triangular factor T of a block reflector $H = I - V^*T^*V^H$ as returned by p?tzrzf.

Syntax

```
call psclarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pdclarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pclarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
call pzclarzt(direct, storev, n, k, v, iv, jv, descv, tau, t, work)
```

Include Files

- C: mkl_scalapack.h

Description

The p?larzt routine forms the triangular factor T of a real/complex block reflector H of order greater than n , which is defined as a product of k elementary reflectors as returned by p?tzrzf.

If $\text{direct} = 'F'$, $H = H(1)*H(2)*\dots*H(k)$, and T is upper triangular;

If $\text{direct} = 'B'$, $H = H(k)*\dots*H(2)*H(1)$, and T is lower triangular.

If $\text{storev} = 'C'$, the vector which defines the elementary reflector $H(i)$, is stored in the i -th column of the array v , and

$H = i - v^*t^*v$.

If $\text{storev} = 'R'$, the vector, which defines the elementary reflector $H(i)$, is stored in the i -th row of the array v , and

$H = i - v^*t^*v$

Currently, only $\text{storev} = 'R'$ and $\text{direct} = 'B'$ are supported.

Input Parameters

<i>direct</i>	(global) CHARACTER. Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if $\text{direct} = 'F'$: $H = H(1)*H(2)*\dots*H(k)$ (Forward, not supported) if $\text{direct} = 'B'$: $H = H(k)*\dots*H(2)*H(1)$ (Backward).
<i>storev</i>	(global) CHARACTER. Specifies how the vectors which defines the elementary reflectors are stored: if $\text{storev} = 'C'$: columnwise (not supported); if $\text{storev} = 'R'$: rowwise.
<i>n</i>	(global). INTEGER. The order of the block reflector H . $n \geq 0$.
<i>k</i>	(global). INTEGER. The order of the triangular factor T (= the number of elementary reflectors). $1 \leq k \leq mb_v (= nb_v)$.
<i>v</i>	REAL for psclarzt DOUBLE PRECISION for pdclarzt

	COMPLEX for <code>pclarzt</code> COMPLEX*16 for <code>pzlarzt</code> . Pointer into the local memory to an array of local <code>DIMENSION(LOCr(iv + k - 1), LOCc(jv + n - 1))</code> . The distributed matrix <code>v</code> contains the Householder vectors. See <i>Application Notes</i> below.
<code>iv, jv</code>	(global) INTEGER. The row and column indices in the global array <code>v</code> indicating the first row and the first column of the submatrix <code>sub(v)</code> , respectively.
<code>descv</code>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix <code>v</code> .
<code>tau</code>	(local) REAL for <code>pslarzt</code> DOUBLE PRECISION for <code>pdlarzt</code> COMPLEX for <code>pclarzt</code> COMPLEX*16 for <code>pzlarzt</code> . Array, <code>DIMENSION LOCr(iv+k-1)</code> if <code>incv = m_v</code> , and <code>LOCc(jv+k-1)</code> otherwise. This array contains the Householder scalars related to the Householder vectors. <code>tau</code> is tied to the distributed matrix <code>v</code> .
<code>work</code>	(local). REAL for <code>pslarzt</code> DOUBLE PRECISION for <code>pdlarzt</code> COMPLEX for <code>pclarzt</code> COMPLEX*16 for <code>pzlarzt</code> . Workspace array, <code>DIMENSION(k * (k-1) / 2)</code> .

Output Parameters

<code>v</code>	REAL for <code>pslarzt</code> DOUBLE PRECISION for <code>pdlarzt</code> COMPLEX for <code>pclarzt</code> COMPLEX*16 for <code>pzlarzt</code> .
<code>t</code>	(local) REAL for <code>pslarzt</code> DOUBLE PRECISION for <code>pdlarzt</code> COMPLEX for <code>pclarzt</code> COMPLEX*16 for <code>pzlarzt</code> . Array, <code>DIMENSION(mb_v, mb_v)</code> . It contains the k -by- k triangular factor of the block reflector associated with <code>v</code> . <code>t</code> is lower triangular.

Application Notes

The shape of the matrix `v` and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

direct='F' and storev='C'

$$v = \begin{bmatrix} v_1 & v_2 & v_3 \\ v_1 & v_2 & v_3 \end{bmatrix}$$

direct='F' and storev='R'

$$\begin{bmatrix} v_1 & v_1 & v_1 & v_1 & v_1 & \dots & \dots & 1 \\ v_2 & v_2 & v_2 & v_2 & v_2 & \dots & \dots & 1 \\ v_3 & v_3 & v_3 & v_3 & v_3 & \dots & \dots & 1 \end{bmatrix}$$

`direct='B' and storev='C'`

```

1
.
. 1
.
. . 1
.
. .
v = . . .

```

direct='B' and storev='R':

$$\begin{bmatrix} & & & & & v \\ 1 & \dots & v_1 & v_1 & v_1 & v_1 \\ . & 1 & \dots & v_2 & v_2 & v_2 & v_2 \\ . & . & 1 & \dots & v_3 & v_3 & v_3 & v_3 \end{bmatrix}$$

p?lascl

Multiplies a general rectangular matrix by a real scalar defined as $C_{\text{to}}/C_{\text{from}}$.

Syntax

```

call psblascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pdblascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pclascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)
call pzblascl(type, cfrom, cto, m, n, a, ia, ja, desca, info)

```

Include Files

- C: mkl_scalapack.h

Description

The `p?lascl` routine multiplies the m -by- n real/complex distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ by the real/complex scalar $cto/cfrom$. This is done without over/underflow as long as the final result $cto \cdot A(i, j) / cfrom$ does not over/underflow. `type` specifies that $\text{sub}(A)$ may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

<code>type</code>	(global) CHARACTER. <code>type</code> indicates the storage type of the input distributed matrix. if <code>type</code> = 'G': $\text{sub}(A)$ is a full matrix, if <code>type</code> = 'L': $\text{sub}(A)$ is a lower triangular matrix, if <code>type</code> = 'U': $\text{sub}(A)$ is an upper triangular matrix, if <code>type</code> = 'H': $\text{sub}(A)$ is an upper Hessenberg matrix.
<code>cfrom, cto</code>	(global) REAL for <code>pslascl/pclascl</code> DOUBLE PRECISION for <code>pdlascl/pzlascl</code> . The distributed matrix $\text{sub}(A)$ is multiplied by $cto/cfrom \cdot A(i,j)$ is computed without over/underflow if the final result $cto \cdot A(i, j) / cfrom$ can be represented without over/underflow. <code>cfrom</code> must be nonzero.
<code>m</code>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<code>n</code>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<code>a</code>	(local input/local output) REAL for <code>pslascl</code> DOUBLE PRECISION for <code>pdlascl</code> COMPLEX for <code>pclascl</code> COMPLEX*16 for <code>pzlascl</code> . Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOCc(ja+n-1))</code> . This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<code>ia, ja</code>	(global) INTEGER. The column and row indices in the global array <code>A</code> indicating the first row and column of the submatrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER . Array of <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix <code>A</code> .

Output Parameters

<code>a</code>	(local). On exit, this array contains the local pieces of the distributed matrix multiplied by <code>cto/cfrom</code> .
<code>info</code>	(local) INTEGER.

if $info = 0$: the execution is successful.
 if $info < 0$: If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$,
 if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?laset

Initializes the offdiagonal elements of a matrix to alpha and the diagonal elements to beta.

Syntax

```
call pslaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pdlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pclaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
call pzlaset(uplo, m, n, alpha, beta, a, ia, ja, desca)
```

Include Files

- C: mkl_scalapack.h

Description

The p?laset routine initializes an m -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ to β on the diagonal and α on the offdiagonals.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies the part of the distributed matrix $\text{sub}(A)$ to be set: if $uplo = 'U'$: upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not changed; if $uplo = 'L'$: lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not changed. Otherwise: all of the matrix $\text{sub}(A)$ is set.
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>alpha</i>	(global). REAL for pslaset DOUBLE PRECISION for pdlaset COMPLEX for pclaset COMPLEX*16 for pzlaset. The constant to which the offdiagonal elements are to be set.
<i>beta</i>	(global). REAL for pslaset DOUBLE PRECISION for pdlaset COMPLEX for pclaset COMPLEX*16 for pzlaset. The constant to which the diagonal elements are to be set.

Output Parameters

a (local).
 REAL for pslaset
 DOUBLE PRECISION for pdlaset
 COMPLEX for pclaset
 COMPLEX*16 for pzaset.
 Pointer into the local memory to an array of DIMENSION (*lld_a*, *LOCc(ja+n-1)*).
 This array contains the local pieces of the distributed matrix sub(*A*) to be set. On exit, the leading *m*-by-*n* submatrix sub(*A*) is set as follows:
 if *uplo* = 'U', *A*(*ia+i-1*, *ja+j-1*) = *alpha*, $1 \leq i \leq j-1$, $1 \leq j \leq n$,
 if *uplo* = 'L', *A*(*ia+i-1*, *ja+j-1*) = *alpha*, $j+1 \leq i \leq m$, $1 \leq j \leq n$,
 otherwise, *A*(*ia+i-1*, *ja+j-1*) = *alpha*, $1 \leq i \leq m$, $1 \leq j \leq n$, *ia+i.ne.ja+j*,
 and, for all *uplo*, *A*(*ia+i-1*, *ja+i-1*) = *beta*, $1 \leq i \leq \min(m, n)$.

ia, ja (global) INTEGER.
 The column and row indices in the global array *A* indicating the first row and column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER.
 Array of DIMENSION (*dlen_*). The array descriptor for the distributed matrix *A*.

p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

```
call pslasmsub(a, desca, i, l, k, smlnum, buf, lwork)
call pdlasmsub(a, desca, i, l, k, smlnum, buf, lwork)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lasmsub routine looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This routine does a global maximum and must be called by all processes.

Input Parameters

a (global).
 REAL for pslasmsub
 DOUBLE PRECISION for pdlasmsub
 Array, DIMENSION (*desca(lld_)*, *).
 On entry, the Hessenberg matrix whose tridiagonal part is being scanned.
 Unchanged on exit.

desca (global and local) INTEGER.
 Array of DIMENSION (*dlen_*). The array descriptor for the distributed matrix *A*.

i (global) INTEGER.

The global location of the bottom of the unreduced submatrix of A . Unchanged on exit.

l (global) INTEGER.
The global location of the top of the unreduced submatrix of A . Unchanged on exit.

smlnum (global)
REAL for pslasmsub
DOUBLE PRECISION for pdlasmsub
On entry, a "small number" for the given matrix. Unchanged on exit. A suggested value for *smlnum* is $\text{slamch('s')} * (n/\text{slamch('p')})$ for pslasmsub or $\text{dlamch('s')} * (n/\text{dlamch('p')})$ for pdlasmsub. See **lamch**.

lwork (global) INTEGER.
On exit, *lwork* is the size of the work buffer.
This must be at least $2 * \text{ceil}(\text{ceil}((i-1)/hbl) / \text{lcm}(nprow, npcol))$. Here **lcm** is least common multiple, and *nprow* \times *npcol* is the logical grid size.

Output Parameters

k (global) INTEGER.
On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $l \leq m \leq i-1$.

buf (local).
REAL for pslasmsub
DOUBLE PRECISION for pdlasmsub
Array of size *lwork*.

p?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
call pslassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pdlassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pclassq(n, x, ix, jx, descx, incx, scale, sumsq)
call pzlassq(n, x, ix, jx, descx, incx, scale, sumsq)
```

Include Files

- C: mkl_scalapack.h

Description

The **p?lassq** routine returns the values *scl* and *smsq* such that

$$\text{scl}^2 * \text{smsq} = x(1)^2 + \dots + x(n)^2 + \text{scale}^2 * \text{sumsq},$$

where $x(i) = \text{sub}(X) = X(ix + (jx-1)*\text{descx}(m_)) + (i - 1)*\text{incx}$ for **pslassq/plassq**,

and $x(i) = \text{abs}(X(ix + (jx-1)*\text{descx}(m_)) + (i - 1)*\text{incx})$ for **pclassq/pzlassq**.

For real routines **pslassq/plassq** the value of *sumsq* is assumed to be non-negative and *scl* returns the value

$$\text{scl} = \max(\text{scale}, \text{abs}(x(i))).$$

For complex routines `plassq/pzlassq` the value of `sumsq` is assumed to be at least unity and the value of `ssq` will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value `scale` is assumed to be non-negative and `scl` returns the value

$$scl = \max_i \left(scale, \max \left(\text{real}(x(i)), \text{imag}(x(i)) \right) \right)$$

For all routines `plassq` values `scale` and `sumsq` must be supplied in `scale` and `sumsq` respectively, and `scale` and `sumsq` are overwritten by `scl` and `ssq` respectively.

All routines `plassq` make only one pass through the vector `sub(x)`.

Input Parameters

<code>n</code>	(global) INTEGER. The length of the distributed vector <code>sub(x)</code> .
<code>x</code>	REAL for <code>plassq</code> DOUBLE PRECISION for <code>pdlassq</code> COMPLEX for <code>plassq</code> COMPLEX*16 for <code>pzlassq</code> . The vector for which a scaled sum of squares is computed: $x(ix + (jx-1)*m_x + (i - 1)*incx), 1 \leq i \leq n.$
<code>ix</code>	(global) INTEGER. The row index in the global array <code>x</code> indicating the first row of <code>sub(x)</code> .
<code>jx</code>	(global) INTEGER. The column index in the global array <code>x</code> indicating the first column of <code>sub(x)</code> .
<code>descx</code>	(global and local) INTEGER array of DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. The global increment for the elements of <code>x</code> . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> . The argument <code>incx</code> must not equal zero.
<code>scale</code>	(local). REAL for <code>plassq/plassq</code> DOUBLE PRECISION for <code>pdlassq/pzlassq</code> . On entry, the value <code>scale</code> in the equation above.
<code>sumsq</code>	(local) REAL for <code>plassq/plassq</code> DOUBLE PRECISION for <code>pdlassq/pzlassq</code> . On entry, the value <code>sumsq</code> in the equation above.

Output Parameters

<code>scale</code>	(local). On exit, <code>scale</code> is overwritten with <code>scl</code> , the scaling factor for the sum of squares.
<code>sumsq</code>	(local). On exit, <code>sumsq</code> is overwritten with the value <code>smsq</code> , the basic sum of squares from which <code>scl</code> has been factored out.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
call psblaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pdblaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pclaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
call pzblaswp(direc, rowcol, n, a, ia, ja, desca, k1, k2, ipiv)
```

Include Files

- C:\mkl_scalapack.h

Description

The p?laswp routine performs a series of row or column interchanges on the distributed matrix $\text{sub}(A)=A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$. One interchange is initiated for each of rows or columns k_1 through k_2 of $\text{sub}(A)$. This routine assumes that the pivoting information has already been broadcast along the process row or column. Also note that this routine will only work for k_1-k_2 being in the same mb (or nb) block. If you want to pivot a full matrix, use p?lapiv.

Input Parameters

<i>direc</i>	(global) CHARACTER. Specifies in which order the permutation is applied: = 'F' - forward, = 'B' - backward.
<i>rowcol</i>	(global) CHARACTER. Specifies if the rows or columns are permuted: = 'R' - rows, = 'C' - columns.
<i>n</i>	(global) INTEGER. If <i>rowcol</i> ='R', the length of the rows of the distributed matrix $A(*, \text{ja}:\text{ja}+n-1)$ to be permuted; If <i>rowcol</i> ='C', the length of the columns of the distributed matrix $A(\text{ia}:\text{ia}+n-1, *)$ to be permuted;
<i>a</i>	(local) REAL for psblaswp DOUBLE PRECISION for pdblaswp COMPLEX for pclaswp COMPLEX*16 for pzblaswp. Pointer into the local memory to an array of DIMENSION (<i>lld_a</i> , *). On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of $\text{sub}(A)$.
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of $\text{sub}(A)$.
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

<i>k1</i>	(global) INTEGER. The first element of <i>ipiv</i> for which a row or column interchange will be done.
<i>k2</i>	(global) INTEGER. The last element of <i>ipiv</i> for which a row or column interchange will be done.
<i>ipiv</i>	(local) INTEGER. Array, DIMENSION $\text{LOCr}(m_a) + mb_a$ for row pivoting and $\text{LOCr}(n_a) + nb_a$ for column pivoting. This array is tied to the matrix <i>A</i> , $ipiv(k)=l$ implies rows (or columns) <i>k</i> and <i>l</i> are to be interchanged.

Output Parameters

<i>A</i>	(local) REAL for <i>pslaswp</i> DOUBLE PRECISION for <i>pdlaswp</i> COMPLEX for <i>pclaswp</i> COMPLEX*16 for <i>pzlaswp</i> . On exit, the permuted distributed matrix.
----------	---

p?latra

Computes the trace of a general square distributed matrix.

Syntax

```
val = pslatra(n, a, ia, ja, desca)
val = pdlatra(n, a, ia, ja, desca)
val = pclatra(n, a, ia, ja, desca)
val = pzlatra(n, a, ia, ja, desca)
```

Include Files

- C: mkl_scalapack.h

Description

This function computes the trace of an *n*-by-*n* distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$. The result is left on every process of the grid.

Input Parameters

<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>a</i>	(local). Real for <i>pslatra</i> DOUBLE PRECISION for <i>pdlatra</i> COMPLEX for <i>pclatra</i> COMPLEX*16 for <i>pzlatra</i> . Pointer into the local memory to an array of $\text{DIMENSION}(lld_a, \text{LOCc}(ja+n-1))$ containing the local pieces of the distributed matrix, the trace of which is to be computed.

<i>ia, ja</i>	(global) INTEGER. The row and column indices respectively in the global array <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>val</i>	The value returned by the function.
------------	-------------------------------------

p?latrd

Reduces the first *nb* rows and columns of a symmetric/Hermitian matrix *A* to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
call pslatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pdlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pclatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
call pzlatrd(uplo, n, nb, a, ia, ja, desca, d, e, tau, w, iw, jw, descw, work)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?latrd` routine reduces *nb* rows and columns of a real symmetric or complex Hermitian matrix $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$ to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation $Q^* \text{sub}(A) * Q$, and returns the matrices *V* and *W*, which are needed to apply the transformation to the unreduced part of $\text{sub}(A)$.

If *uplo* = U, `p?latrd` reduces the last *nb* rows and columns of a matrix, of which the upper triangle is supplied;

if *uplo* = L, `p?latrd` reduces the first *nb* rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary routine called by `p?sytrd/p?hetrd`.

Input Parameters

<i>uplo</i>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored: = 'U': Upper triangular = 'L': Lower triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>nb</i>	(global) INTEGER. The number of rows and columns to be reduced.
<i>a</i>	REAL for pslatrd

DOUBLE PRECISION for pdlatrd
 COMPLEX for pclatrd
 COMPLEX*16 for pzlatrd.
 Pointer into the local memory to an array of DIMENSION (lld_a , $LOCc(ja+n-1)$).
 On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix $\text{sub}(A)$.
 If $uplo = \text{U}$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.
 If $uplo = \text{L}$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.

ia
 (global) INTEGER.
 The row index in the global array A indicating the first row of $\text{sub}(A)$.

ja
 (global) INTEGER.
 The column index in the global array A indicating the first column of $\text{sub}(A)$.

descA
 (global and local) INTEGER array of DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .

iw
 (global) INTEGER.
 The row index in the global array w indicating the first row of $\text{sub}(w)$.

jw
 (global) INTEGER.
 The column index in the global array w indicating the first column of $\text{sub}(w)$.

descw
 (global and local) INTEGER array of DIMENSION ($dlen_$). The array descriptor for the distributed matrix w .

work
 (local)
 REAL for pslatrd
 DOUBLE PRECISION for pdlatrd
 COMPLEX for pclatrd
 COMPLEX*16 for pzlatrd.
 Workspace array of DIMENSION (nb_a).

Output Parameters

a
 (local)
 On exit, if $uplo = \text{'U'}$, the last nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $\text{sub}(A)$; the elements above the diagonal with the array τ_{au} represent the orthogonal/unitary matrix Q as a product of elementary reflectors;
 if $uplo = \text{'L'}$, the first nb columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of $\text{sub}(A)$; the elements below the diagonal with the array τ_{au} represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

d
 (local)
 REAL for pslatrd/pclatrd
 DOUBLE PRECISION for pdlatrd/pzlatrd.
 Array, DIMENSION $LOCc(ja+n-1)$.
 The diagonal elements of the tridiagonal matrix T : $d(i) = a(i,i)$. *d* is tied to the distributed matrix A .

e
 (local)

```

REAL for pslatrd/pclatrd
DOUBLE PRECISION for pdlatrd/pzlatrd.
Array, DIMENSION LOCc(ja+n-1) if uplo = 'U', LOCc(ja+n-2)
otherwise.
The off-diagonal elements of the tridiagonal matrix T:
e(i) = a(i, i + 1) if uplo = 'U',
e(i) = a(i + 1, i) if uplo = L.
e is tied to the distributed matrix A.

tau
(local)
REAL for pslatrd
DOUBLE PRECISION for pdlatrd
COMPLEX for pclatrd
COMPLEX*16 for pzlatrd.
Array, DIMENSION LOCc(ja+n-1). This array contains the scalar factors
tau of the elementary reflectors. tau is tied to the distributed matrix A.

w
(local)
REAL for pslatrd
DOUBLE PRECISION for pdlatrd
COMPLEX for pclatrd
COMPLEX*16 for pzlatrd.
Pointer into the local memory to an array of DIMENSION (lld_w, nb_w). This
array contains the local pieces of the n-by-nb_w matrix w required to update
the unreduced part of sub(A).

```

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-1, ja+i)$, and τ in $\tau(ja+i-1)$.

If $uplo = L$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v^T,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1: ia+n-1, ja+i-1)$, and τ in $\tau(ja+i-1)$.

The elements of the vectors v together form the n -by- nb matrix v which is needed, with w , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$ update of the form:

$$\text{sub}(A) := \text{sub}(A) - vw^T - wv^T.$$

The contents of a on exit are illustrated by the following examples with

$n = 5$ and $nb = 2$:

$$\begin{array}{ll}
 \text{if } uplo=\text{'U'}: & \text{if } uplo=\text{'L'}: \\
 \left[\begin{array}{ccccc} a & a & a & v_4 & v_5 \\ a & a & v_4 & v_5 & \\ a & 1 & v_5 & & \\ d & 1 & & & \\ d & & & & \end{array} \right] & \left[\begin{array}{ccccc} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{array} \right]
 \end{array}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

p?latrs

Solves a triangular system of equations with the scale factor set to prevent overflow.

Syntax

```

call pslatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)

call pdlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)

call pclatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)

call pzlatrs(uplo, trans, diag, normin, n, a, ia, ja, desca, x, ix, jx, descx, scale,
cnorm, work)

```

Include Files

- C: mkl_scalapack.h

Description

The `p?latrs` routine solves a triangular system of equations $Ax = Sb$, $A^T x = Sb$ or $A^H x = Sb$, where S is a scale factor set to prevent overflow. The description of the routine will be extended in the future releases.

Input Parameters

<code>uplo</code>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<code>trans</code>	CHARACTER*1. Specifies the operation applied to Ax . = 'N': Solve $Ax = s*b$ (no transpose) = 'T': Solve $A^T x = s*b$ (transpose) = 'C': Solve $A^H x = s*b$ (conjugate transpose), where s - is a scale factor
<code>diag</code>	CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular

= 'U': Unit triangular
`normin`
 CHARACTER*1.
 Specifies whether `cnorm` has been set or not.
 = 'Y': `cnorm` contains the column norms on entry;
 = 'N': `cnorm` is not set on entry. On exit, the norms will be computed and stored in `cnorm`.
`n`
 INTEGER.
 The order of the matrix `A`. $n \geq 0$
`a`
 REAL for `pslatrs/pclatrs`
 DOUBLE PRECISION for `pdlatrs/pzlatrs`
 Array, DIMENSION (`lda, n`). Contains the triangular matrix `A`.
 If `uplo` = 'U', the leading n -by- n upper triangular part of the array `a` contains the upper triangular matrix, and the strictly lower triangular part of `a` is not referenced.
 If `uplo` = 'L', the leading n -by- n lower triangular part of the array `a` contains the lower triangular matrix, and the strictly upper triangular part of `a` is not referenced.
 If `diag` = 'U', the diagonal elements of `a` are also not referenced and are assumed to be 1.
`ia, ja`
 (global) INTEGER. The row and column indices in the global array `a` indicating the first row and the first column of the submatrix `A`, respectively.
`descA`
 (global and local) INTEGER array, DIMENSION (`dlen_`). The array descriptor for the distributed matrix `A`.
`x`
 REAL for `pslatrs/pclatrs`
 DOUBLE PRECISION for `pdlatrs/pzlatrs`
 Array, DIMENSION (n). On entry, the right hand side `b` of the triangular system.
`ix`
 (global) INTEGER. The row index in the global array `x` indicating the first row of `sub(x)`.
`jx`
 (global) INTEGER.
 The column index in the global array `x` indicating the first column of `sub(x)`.
`descX`
 (global and local) INTEGER.
 Array, DIMENSION (`dlen_`). The array descriptor for the distributed matrix `X`.
`cnorm`
 REAL for `pslatrs/pclatrs`
 DOUBLE PRECISION for `pdlatrs/pzlatrs`.
 Array, DIMENSION (n). If `normin` = 'Y', `cnorm` is an input argument and `cnorm(j)` contains the norm of the off-diagonal part of the j -th column of `A`. If `trans` = 'N', `cnorm(j)` must be greater than or equal to the infinity-norm, and if `trans` = 'T' or 'C', `cnorm(j)` must be greater than or equal to the 1-norm.
`work`
 (local).
 REAL for `pslatrs`
 DOUBLE PRECISION for `pdlatrs`
 COMPLEX for `pclatrs`
 COMPLEX*16 for `pzlatrs`.
 Temporary workspace.

Output Parameters

`x` On exit, `x` is overwritten by the solution vector `x`.

<i>scale</i>	REAL for pslatrs/pclatrs DOUBLE PRECISION for pdlatrs/pzlatrs. Array, DIMENSION (<i>lda</i> , <i>n</i>). The scaling factor <i>s</i> for the triangular system as described above. If <i>scale</i> = 0, the matrix <i>A</i> is singular or badly scaled, and the vector <i>x</i> is an exact or approximate solution to <i>AX</i> = 0.
<i>cnorm</i>	If <i>normin</i> = 'N', <i>cnorm</i> is an output argument and <i>cnorm(j)</i> returns the 1-norm of the off-diagonal part of the <i>j</i> -th column of <i>A</i> .

p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

Syntax

```
call pslatrz(m, n, l, a, ia, ja, desca, tau, work)
call pdlatrz(m, n, l, a, ia, ja, desca, tau, work)
call pclatrz(m, n, l, a, ia, ja, desca, tau, work)
call pzlatrz(m, n, l, a, ia, ja, desca, tau, work)
```

Include Files

- C: mkl_scalapack.h

Description

The p?latrz routine reduces the *m*-by-*n* (*m* \leq *n*) real/complex upper trapezoidal matrix $\text{sub}(A) = [A(ia:ia+m-1, ja:ja+m-1) \ A(ia:ia+m-1, ja+n-1:ja+n-1)]$ to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix $\text{sub}(A)$ is factored as

$$\text{sub}(A) = (R \ 0) * Z,$$

where *Z* is an *n*-by-*n* orthogonal/unitary matrix and *R* is an *m*-by-*m* upper triangular matrix.

Input Parameters

<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(A)$. <i>m</i> \geq 0.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(A)$. <i>n</i> \geq 0.
<i>l</i>	(global) INTEGER. The number of columns of the distributed submatrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. <i>l</i> $>$ 0.
<i>a</i>	(local) REAL for pslatrz DOUBLE PRECISION for pdlatrz COMPLEX for pclatrz COMPLEX*16 for pzlatrz.

Pointer into the local memory to an array of `DIMENSION(1ld_a, LOCc(ja +n-1))`. On entry, the local pieces of the m -by- n distributed matrix `sub(A)`, which is to be factored.

`ia`

(global) INTEGER.

The row index in the global array `A` indicating the first row of `sub(A)`.`ja`

(global) INTEGER.

The column index in the global array `A` indicating the first column of `sub(A)`.`desca`(global and local) INTEGER array of `DIMENSION(dlen_)`.The array descriptor for the distributed matrix `A`.`work`

(local)

REAL for `pslatrz`DOUBLE PRECISION for `pdlatrz`COMPLEX for `pclatrz`COMPLEX*16 for `pzlatrz`.Workspace array, `DIMENSION(1work)`. $1work \geq nq0 + \max(1, mp0)$, where`iroff = mod(ia-1, mb_a),``icoff = mod(ja-1, nb_a),``iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),``iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),``mp0 = numroc(m+iroff, mb_a, myrow, iarow, nprow),``nq0 = numroc(n+icoff, nb_a, mycol, iacol, npcol),`numroc, `indxg2p`, and `numroc` are ScaLAPACK tool functions; `myrow`,`mycol`, `nprow`, and `npcol` can be determined by calling the subroutine`blacs_gridinfo`.

Output Parameters

`a`

On exit, the leading m -by- m upper triangular part of `sub(A)` contains the upper triangular matrix `R`, and elements $n-1+1$ to n of the first m rows of `sub(A)`, with the array `tau`, represent the orthogonal/unitary matrix `Z` as a product of m elementary reflectors.

`tau`

(local)

REAL for `pslatrz`DOUBLE PRECISION for `pdlatrz`COMPLEX for `pclatrz`COMPLEX*16 for `pzlatrz`.

Array, `DIMENSION(LOCr(ja+m-1))`. This array contains the scalar factors of the elementary reflectors. `tau` is tied to the distributed matrix `A`.

Application Notes

The factorization is obtained by Householder's method. The k -th transformation matrix, $Z(k)$, which is used (or, in case of complex routines, whose conjugate transpose is used) to introduce zeros into the $(m - k + 1)$ -th row of `sub(A)`, is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - tau * u(k) * u(k)', \quad u(k) = \begin{bmatrix} I \\ 0 \\ z(k) \end{bmatrix}$$

tau is a scalar and $z(k)$ is an $(n-m)$ -element vector. tau and $z(k)$ are chosen to annihilate the elements of the k -th row of $\text{sub}(A)$. The scalar tau is returned in the k -th element of tau and the vector $u(k)$ in the k -th row of $\text{sub}(A)$, such that the elements of $z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of $\text{sub}(A)$.

Z is given by

$$Z = Z(1)Z(2)\dots Z(m).$$

p?lauu2

Computes the product U^*U' or L'^*L , where U and L are upper or lower triangular matrices (local unblocked algorithm).

Syntax

```
call pslauu2(uplo, n, a, ia, ja, desca)
call pdlauu2(uplo, n, a, ia, ja, desca)
call pclauu2(uplo, n, a, ia, ja, desca)
call pzlauu2(uplo, n, a, ia, ja, desca)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lauu2 routine computes the product U^*U' or L'^*L , where the triangular factor U or L is stored in the upper or lower triangular part of the distributed matrix

$$\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1).$$

If $uplo = 'U'$ or ' u ', then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$.

If $uplo = 'L'$ or ' l ', then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this routine, the matrix to operate on should be strictly local to one process.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the triangular factor stored in the <i>matrix</i> $\text{sub}(A)$ is upper or lower triangular: = U : upper triangular = L : lower triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the triangular factor U or L . $n \geq 0$.
<i>a</i>	(local) REAL for pslauu2 DOUBLE PRECISION for pdlauu2

COMPLEX for `pclauu2`
 COMPLEX*16 for `pzlauu2`.
 Pointer into the local memory to an array of DIMENSION (`lld_a`, `LOCc(ja+n-1)`). On entry, the local pieces of the triangular factor U or L .

`ia` (global) INTEGER.
 The row index in the global array A indicating the first row of $\text{sub}(A)$.

`ja` (global) INTEGER.
 The column index in the global array A indicating the first column of $\text{sub}(A)$.

`desca` (global and local) INTEGER array of DIMENSION (`dlen_`). The array descriptor for the distributed matrix A .

Output Parameters

`a` (local)
 On exit, if `uplo = 'U'`, the upper triangle of the distributed matrix $\text{sub}(A)$ is overwritten with the upper triangle of the product U^*U ; if `uplo = 'L'`, the lower triangle of $\text{sub}(A)$ is overwritten with the lower triangle of the product L^*L .

p?lauum

Computes the product U^*U' or L^*L' , where U and L are upper or lower triangular matrices.

Syntax

```
call pslauum(uplo, n, a, ia, ja, desca)
call pdlauum(uplo, n, a, ia, ja, desca)
call pclauum(uplo, n, a, ia, ja, desca)
call pzlauum(uplo, n, a, ia, ja, desca)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lauum` routine computes the product U^*U' or L^*L' , where the triangular factor U or L is stored in the upper or lower triangular part of the matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If `uplo = 'U'` or `'u'`, then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$. If `uplo = 'L'` or `'l'`, then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

`uplo` (global) CHARACTER*1.
 Specifies whether the triangular factor stored in the matrix $\text{sub}(A)$ is upper or lower triangular:
 $= 'U'$: upper triangular
 $= 'L'$: lower triangular.

`n` (global) INTEGER.
 The number of rows and columns to be operated on, that is, the order of the triangular factor U or L . $n \geq 0$.

<i>a</i>	(local) REAL for pslauum DOUBLE PRECISION for pdlauum COMPLEX for pclauum COMPLEX*16 for pzlaum. Pointer into the local memory to an array of DIMENSION(<i>lld_a</i> , <i>LOCc(ja</i> <i>+n-1)</i>). On entry, the local pieces of the triangular factor <i>U</i> or <i>L</i> .
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dLen_</i>). The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	(local) On exit, if <i>uplo</i> = 'U', the upper triangle of the distributed matrix sub(<i>A</i>) is overwritten with the upper triangle of the product <i>U</i> * <i>U</i> ; if <i>uplo</i> = 'L', the lower triangle of sub(<i>A</i>) is overwritten with the lower triangle of the product <i>L</i> ' * <i>L</i> .
----------	--

p?lawil

Forms the Wilkinson transform.

Syntax

```
call pslawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
call pdlawil(ii, jj, m, a, desca, h44, h33, h43h34, v)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lawil routine gets the transform given by *h44*, *h33*, and *h43h34* into *v* starting at row *m*.

Input Parameters

<i>ii</i>	(global) INTEGER. Row owner of <i>h(m+2, m+2)</i> .
<i>jj</i>	(global) INTEGER. Column owner of <i>h(m+2, m+2)</i> .
<i>m</i>	(global) INTEGER. On entry, the location from where the transform starts (row <i>m</i>). Unchanged on exit.
<i>a</i>	(global) REAL for pslawil DOUBLE PRECISION for pdlawil Array, DIMENSION (<i>desca(lld_)</i> ,*). On entry, the Hessenberg matrix. Unchanged on exit.
<i>desca</i>	(global and local) INTEGER

Array of DIMENSION (*dlen_*). The array descriptor for the distributed matrix
 A. Unchanged on exit.

h43h34

(global)
 REAL for pslawil
 DOUBLE PRECISION for pdlawil
 These three values are for the double shift QR iteration. Unchanged on exit.

Output Parameters

v

(global)
 REAL for pslawil
 DOUBLE PRECISION for pdlawil
 Array of size 3 that contains the transform on output.

p?org2l/p?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

```
call psorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2l(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?org2l/p?ung2l routine generates an *m*-by-*n* real/complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last *n* columns of a product of *k* elementary reflectors of order *m*:

$Q = H(k) * \dots * H(2) * H(1)$ as returned by p?geqlf.

Input Parameters

m

(global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q. $m \geq 0$.

n

(global) INTEGER.
 The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q. $m \geq n \geq 0$.

k

(global) INTEGER.
 The number of elementary reflectors whose product defines the matrix Q.
 $n \geq k \geq 0$.

a

REAL for psorg2l
 DOUBLE PRECISION for pdorg2l
 COMPLEX for pcung2l
 COMPLEX*16 for pzung2l.

Pointer into the local memory to an array, DIMENSION ($l1d_a$, $LOCc(ja + n - 1)$).
 On entry, the j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja + n - k \leq j \leq ja + n - k$, as returned by [p?geqlf](#) in the k columns of its *distributed matrix* argument $A(ia:*, ja + n - k : ja + n - 1)$.

ia (global) INTEGER.
 The row index in the global array A indicating the first row of sub(A).

ja (global) INTEGER.
 The column index in the global array A indicating the first column of sub(A).

$desca$ (global and local) INTEGER array of DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .

tau (local)
 REAL for psorg2l
 DOUBLE PRECISION for pdorg2l
 COMPLEX for pcung2l
 COMPLEX*16 for pzung2l.
 Array, DIMENSION $LOCc(ja + n - 1)$.
 This array contains the scalar factor $tau(j)$ of the elementary reflector $H(j)$, as returned by [p?geqlf](#).

$work$ (local)
 REAL for psorg2l
 DOUBLE PRECISION for pdorg2l
 COMPLEX for pcung2l
 COMPLEX*16 for pzung2l.
 Workspace array, DIMENSION ($lwork$).

$lwork$ (local or global) INTEGER.
 The dimension of the array $work$.
 $lwork$ is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where
 $iroffa = \text{mod}(ia - 1, mb_a),$
 $icoffa = \text{mod}(ja - 1, nb_a),$
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow),$
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol),$
 $mpa0 = \text{numroc}(m + iroffa, mb_a, myrow, iarow, nprow),$
 $nqa0 = \text{numroc}(n + icoffa, nb_a, mycol, iacol, npcol).$
 indxg2p and numroc are ScalAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the subroutine `blacs_gridinfo`. If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a On exit, this array contains the local pieces of the m -by- n distributed matrix Q .

$work$ On exit, $work(1)$ returns the minimal and optimal $lwork$.

$info$ (local) INTEGER.
 = 0: successful exit
 < 0: if the i -th argument is an array and the j -entry had an illegal value,

then $info = - (i*100 + j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

p?org2r/p?ung2r

Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).

Syntax

```
call psorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorg2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzung2r(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?org2r/p?ung2r routine generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m :

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by p?geqrf.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $m \geq n \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	REAL for psorg2r DOUBLE PRECISION for pdorg2r COMPLEX for pcung2r COMPLEX*16 for pzung2r. Pointer into the local memory to an array, DIMENSION(lld_a, LOCc(ja+n-1)). On entry, the j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of sub(A).

<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of <i>sub(A)</i> .
<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for <i>psorg2r</i> DOUBLE PRECISION for <i>pdorg2r</i> COMPLEX for <i>pcung2r</i> COMPLEX*16 for <i>pzung2r</i> . <i>Array</i> , DIMENSION <i>LOCc(ja+k-1)</i> . This array contains the scalar factor <i>tau(j)</i> of the elementary reflector <i>H(j)</i> , as returned by <i>p?geqrf</i> . This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) REAL for <i>psorg2r</i> DOUBLE PRECISION for <i>pdorg2r</i> COMPLEX for <i>pcung2r</i> COMPLEX*16 for <i>pzung2r</i> . Workspace array , DIMENSION (<i>lwork</i>). <i>lwork</i>
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where <i>iroffa</i> = mod(<i>ia</i> -1, <i>mb_a</i>), <i>icoffa</i> = mod(<i>ja</i> -1, <i>nb_a</i>), <i>iarow</i> = <i>indxg2p(ia, mb_a, myrow, rsrc_a, nprow)</i> , <i>iacol</i> = <i>indxg2p(ja, nb_a, mycol, csrc_a, npcol)</i> , <i>mpa0</i> = <i>numroc(m+iroffa, mb_a, myrow, iarow, nprow)</i> , <i>nqa0</i> = <i>numroc(n+icoffa, nb_a, mycol, iacol, npcol)</i> . <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the subroutine <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

Output Parameters

<i>a</i>	On exit, this array contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
<i>work</i>	On exit, <i>work(1)</i> returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER. = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (i*100+j), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = -i.

p?orgl2/p?unql2

Generates all or part of the orthogonal/unitary matrix *Q* from an *LQ* factorization determined by *p?gelqf* (unblocked algorithm).

Syntax

```
call psorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungl2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?orgl2/p?ungl2` routine generates a m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = H(k) * \dots * H(2) * H(1)$ (for real flavors),

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ (for complex flavors) as returned by [p?gelqf](#).

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $n \geq m \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for <code>psorgl2</code> DOUBLE PRECISION for <code>pdorgl2</code> COMPLEX for <code>pcungl2</code> COMPLEX*16 for <code>pzungl2</code> . Pointer into the local memory to an array, DIMENSION (<code>lld_a, LOCc(ja+n-1)</code>). On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gelqf in the k rows of its <i>distributed matrix</i> argument $A(ia:ia+k-1, ja:*)$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of sub(A).
ja	(global) INTEGER. The column index in the global array A indicating the first column of sub(A).
$desca$	(global and local) INTEGER array of DIMENSION (<code>dlen_</code>). The array descriptor for the distributed matrix A .
tau	(local) REAL for <code>psorgl2</code> DOUBLE PRECISION for <code>pdorgl2</code> COMPLEX for <code>pcungl2</code> COMPLEX*16 for <code>pzungl2</code> .

Array, DIMENSION $LOCr(ja+k-1)$. This array contains the scalar factors τ_{ij} of the elementary reflectors $H(i)$, as returned by [p?gelqf](#). This array is tied to the distributed matrix A .

WORK

(local)
REAL for [psorgl2](#)
DOUBLE PRECISION for [pdorgl2](#)
COMPLEX for [pcungl2](#)
COMPLEX*16 for [pzungl2](#).
Workspace array, DIMENSION ($lwork$).

$lwork$

(local or global) INTEGER.
The dimension of the array $work$.

$lwork$ is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where

```
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),
mpa0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
nqa0 = numroc(n+icoffa, nb_a, mycol, iacol, npcol).
indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow,
and npcol can be determined by calling the subroutine blacs_gridinfo.
If  $lwork = -1$ , then  $lwork$  is global input and a workspace query is
assumed; the routine only calculates the minimum and optimal size for all
work arrays. Each of these values is returned in the first entry of the
corresponding work array, and no error message is issued by pxerbla.
```

Output Parameters

a

On exit, this array contains the local pieces of the m -by- n distributed matrix Q .

$work$

On exit, $work(1)$ returns the minimal and optimal $lwork$.

$info$

(local) INTEGER.
= 0: successful exit
< 0: if the i -th argument is an array and the j -entry had an illegal value,
then $info = -(i*100+j)$,
if the i -th argument is a scalar and had an illegal value,
then $info = -i$.

p?orgr2/p?ungr2

Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by [p?gerqf](#) (unblocked algorithm).

Syntax

```
call psorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pdorgr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pcungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
call pzungr2(m, n, k, a, ia, ja, desca, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?orgr2/p?ungr2 routine generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1) * H(2) * \dots * H(k)$ (for real flavors);

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ (for complex flavors) as returned by p?gerqf.

Input Parameters

m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix Q . $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix Q . $n \geq m \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	REAL for psorgr2 DOUBLE PRECISION for pdorgr2 COMPLEX for pcungqr2 COMPLEX*16 for pzunqr2. Pointer into the local memory to an array, DIMENSION(1:d_a, LOCr(ja+n-1)). On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by p?gerqf in the k rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of sub(A).
ja	(global) INTEGER. The column index in the global array A indicating the first column of sub(A).
$desca$	(global and local) INTEGER array of DIMENSION (dlen_). The array descriptor for the distributed matrix A .
tau	(local) REAL for psorgr2 DOUBLE PRECISION for pdorgr2 COMPLEX for pcungqr2 COMPLEX*16 for pzunqr2. Array, DIMENSION LOCr(ja+m-1). This array contains the scalar factors τ_{ai} of the elementary reflectors $H(i)$, as returned by p?gerqf. This array is tied to the distributed matrix A .
$work$	(local) REAL for psorgr2 DOUBLE PRECISION for pdorgr2 COMPLEX for pcungqr2 COMPLEX*16 for pzunqr2.

Workspace array, DIMENSION (*lwork*).

lwork

(local or global) INTEGER.

The dimension of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where $iroffa = \text{mod}(ia-1, mb_a)$, $icoffa = \text{mod}(ja-1, nb_a)$,
 $iarow = \text{indxg2p}(ia, mb_a, myrow, rsrc_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb_a, mycol, csrc_a, npcol)$,
 $mpa0 = \text{numroc}(m+iroffa, mb_a, myrow, iarow, nprow)$,
 $nqa0 = \text{numroc}(n+icoffa, nb_a, mycol, iacol, npcol)$.
indxg2p and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the subroutine *blacs_gridinfo*. If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work

On exit, *work*(1) returns the minimal and optimal *lwork*.

info

(local) INTEGER.

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = - (i*100+j),

if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?orm2l/p?unm2l

Multiples a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

```
call psorm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pdorm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pcunm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pzunm2l(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?orm2l/p?unm2l routine overwrites the general real/complex *m*-by-*n* distributed matrix sub $(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^* \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'N'$, or
 $Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors), or
 $\text{sub}(C)^*Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or
 $\text{sub}(C)^*Q^T / \text{sub}(C)^*Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by [p?geqlf](#). Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER. = ' <i>L</i> ': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = ' <i>R</i> ': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER. = ' <i>N</i> ': apply Q (no transpose) = ' <i>T</i> ': apply Q^T (transpose, for real flavors) = ' <i>C</i> ': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
<i>n</i>	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
<i>k</i>	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $\text{side} = 'L'$, $m \geq k \geq 0$; if $\text{side} = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) REAL for psorm2l DOUBLE PRECISION for pdorm2l COMPLEX for pcunm2l COMPLEX*16 for pzunm2l . Pointer into the local memory to an array, DIMENSION(<i>lld_a</i> , <i>LOCc(ja+k-1)</i>). On entry, the <i>j</i> -th row must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqlf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the routine but restored on exit. If $\text{side} = 'L'$, <i>lld_a</i> $\geq \max(1, LOCr(ia+m-1))$, if $\text{side} = 'R'$, <i>lld_a</i> $\geq \max(1, LOCr(ia+n-1))$.
<i>ia</i>	(global) INTEGER. The row index in the global array <i>A</i> indicating the first row of $\text{sub}(A)$.
<i>ja</i>	(global) INTEGER. The column index in the global array <i>A</i> indicating the first column of $\text{sub}(A)$.

<i>desca</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>A</i> .
<i>tau</i>	(local) REAL for psorm2l DOUBLE PRECISION for pdorm2l COMPLEX for pcunm2l COMPLEX*16 for pzunm2l. Array, DIMENSION $LOC(ja+n-1)$. This array contains the scalar factor τ_{ij} of the elementary reflector $H(j)$, as returned by p?geqlf . This array is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) REAL for psorm2l DOUBLE PRECISION for pdorm2l COMPLEX for pcunm2l COMPLEX*16 for pzunm2l. Pointer into the local memory to an array, DIMENSION (<i>lld_c</i> , $LOC(jc+n-1)$). On entry, the local pieces of the distributed matrix sub (<i>C</i>).
<i>ic</i>	(global) INTEGER. The row index in the global array <i>C</i> indicating the first row of sub(<i>C</i>).
<i>jc</i>	(global) INTEGER. The column index in the global array <i>C</i> indicating the first column of sub(<i>C</i>).
<i>descC</i>	(global and local) INTEGER array of DIMENSION (<i>dlen_</i>). The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) REAL for psorm2l DOUBLE PRECISION for pdorm2l COMPLEX for pcunm2l COMPLEX*16 for pzunm2l. Workspace array, DIMENSION (<i>lwork</i>). On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>lwork</i>	(local or global) INTEGER. The dimension of the array <i>work</i> . <i>lwork</i> is local input and must be at least <pre>if side = 'L', lwork ≥ mpc0 + max(1, nqc0), if side = 'R', lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n +icoffc, nb_a, 0, 0, npcol), nb_a, 0, 0, lcmq)), where lcmq = lcm/npcol, lcm = iclm(nprow, npcol), iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1, nb_c), icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow), iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol), Mqc0 = numroc(m+icoffc, nb_c, mycol, icrow, nprow), Npc0 = numroc(n+iroffc, mb_c, myrow, iccol, npcol), ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol, nprow, and npcol can be determined by calling the subroutine blacs_gridinfo.</pre>

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

c	On exit, c is overwritten by $Q^* \text{sub}(C)$, or $Q^T \text{sub}(C) / Q^H \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$
$work$	On exit, $work(1)$ returns the minimal and optimal $lwork$.
$info$	(local) INTEGER. = 0: successful exit < 0: if the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

NOTE The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

```
If side = 'L', ( mb_a.eq.mb_c .AND. iroffa.eq.iroffc .AND. iarow.eq.icrow )
If side = 'R', ( mb_a.eq.nb_c .AND. iroffa.eq.iroffc ).
```

p?orm2r/p?unm2r

Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqrf (unblocked algorithm).

Syntax

```
call psorm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pdorm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pcunm2r(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,

Description

The p?orm2r/p?unm2r routine overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^* \text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by [p?geqrf](#). Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

side	(global) CHARACTER. = ' L ': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = ' R ': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
trans	(global) CHARACTER. = ' N ': apply Q (no transpose) = ' T ': apply Q^T (transpose, for real flavors) = ' C ': apply Q^H (conjugate transpose, for complex flavors)
m	(global) INTEGER. The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.
n	(global) INTEGER. The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.
k	(global) INTEGER. The number of elementary reflectors whose product defines the matrix Q . If $\text{side} = 'L'$, $m \geq k \geq 0$; if $\text{side} = 'R'$, $n \geq k \geq 0$.
a	(local) REAL for psorm2r DOUBLE PRECISION for pdorm2r COMPLEX for pcunm2r COMPLEX*16 for pzunm2r . Pointer into the local memory to an array, $\text{DIMENSION}(lld_a, LOCc(ja+k-1))$. On entry, the j -th column must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja: ja+k-1)$. The argument $A(ia:*, ja: ja+k-1)$ is modified by the routine but restored on exit. If $\text{side} = 'L'$, $lld_a \geq \max(1, LOCr(ia+m-1))$, if $\text{side} = 'R'$, $lld_a \geq \max(1, LOCr(ia+n-1))$.
ia	(global) INTEGER. The row index in the global array A indicating the first row of $\text{sub}(A)$.
ja	(global) INTEGER. The column index in the global array A indicating the first column of $\text{sub}(A)$.
$desca$	(global and local) INTEGER array of $\text{DIMENSION}(dlen_*)$. The array descriptor for the distributed matrix A .
tau	(local) REAL for psorm2r DOUBLE PRECISION for pdorm2r COMPLEX for pcunm2r

C COMPLEX*16 for pzunm2r.
Array, DIMENSION $LOCc(ja+k-1)$. This array contains the scalar factors $\tau_{au(j)}$ of the elementary reflector $H(j)$, as returned by [p?geqrf](#). This array is tied to the distributed matrix A .

ic (local) REAL for psorm2r
 DOUBLE PRECISION for pdorm2r
 COMPLEX for pcunm2r
 COMPLEX*16 for pzunm2r.
 Pointer into the local memory to an array, DIMENSION(lld_c , $LOCc(jc+n-1)$).
 On entry, the local pieces of the distributed matrix sub (c).

jc (global) INTEGER.
 The row index in the global array c indicating the first row of sub(c).

descC (global) INTEGER.
 The column index in the global array c indicating the first column of sub(c).

work (local) REAL for psorm2r
 DOUBLE PRECISION for pdorm2r
 COMPLEX for pcunm2r
 COMPLEX*16 for pzunm2r.
 Workspace array, DIMENSION ($lwork$).

lwork (local or global) INTEGER.
 The dimension of the array $work$.
 $lwork$ is local input and must be at least
 $\text{if } side = 'L', lwork \geq mpc0 + \max(1, nqc0),$
 $\text{if } side = 'R', lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n + ioffc, nb_a, 0, 0, npcol), nb_a, 0, 0, lcmq)),$
 where
 $lcmq = lcm/npcol,$
 $lcm = iclm(nprow, npcol),$
 $iroffc = \text{mod}(ic-1, mb_c),$
 $icoffc = \text{mod}(jc-1, nb_c),$
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol),$
 $Mqc0 = \text{numroc}(m+iroffc, nb_c, mycol, icrow, nprow),$
 $Npc0 = \text{numroc}(n+icoffc, nb_c, myrow, iccol, npcol),$
 $ilcm, \text{indxg2p}$ and numroc are ScaLAPACK tool functions; $myrow, mycol, nprow$, and $npcol$ can be determined by calling the subroutine blacs_gridinfo .
 If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

C On exit, c is overwritten by $Q^* \text{sub}(C)$, or $Q^{T*} \text{sub}(C) / Q^{H*} \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$

<i>work</i>	On exit, <i>work</i> (1) returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) INTEGER.
	= 0: successful exit
	< 0: if the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>),
	if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

NOTE The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', $(mb_a.eq.mb_c .AND. iroffa.eq.iroffc .AND. iarow.eq.icrow)$
If *side* = 'R', $(mb_a.eq.nb_c .AND. iroffa.eq.iroffc)$.

p?orml2/p?unml2

Multiples a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).

Syntax

```
call psorml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pdorml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pcunml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pzunml2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?orml2/p?unml2 routine overwrites the general real/complex *m*-by-*n* distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^*\text{sub}(C)$ if *side* = 'L' and *trans* = 'N', or

$Q^T\text{sub}(C) / Q^H\text{sub}(C)$ if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

$\text{sub}(C)*Q$ if *side* = 'R' and *trans* = 'N', or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$ if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of *k* elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ (for real flavors)

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ (for complex flavors)

as returned by p?gelqf. Q is of order *m* if *side* = 'L' and of order *n* if *side* = 'R'.

Input Parameters

side (global) CHARACTER.
 = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left,
 = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.

trans (global) CHARACTER.
 = 'N': apply Q (no transpose)
 = 'T': apply Q^T (transpose, for real flavors)
 = 'C': apply Q^H (conjugate transpose, for complex flavors)

m (global) INTEGER.
 The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.

n (global) INTEGER.
 The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.

k (global) INTEGER.
 The number of elementary reflectors whose product defines the matrix Q .
 If *side* = 'L', $m \geq k \geq 0$;
 if *side* = 'R', $n \geq k \geq 0$.

a (local)
 REAL for psorml2
 DOUBLE PRECISION for pdorml2
 COMPLEX for pcunml2
 COMPLEX*16 for pzunml2.
 Pointer into the local memory to an array, DIMENSION
 $(\text{lld}_a, \text{LOCc}(ja+m-1) \text{ if } \text{side}='L',$
 $(\text{lld}_a, \text{LOCc}(ja+n-1) \text{ if } \text{side}='R',$
 where $\text{lld}_a \geq \max(1, \text{LOCr}(ia+k-1))$.
 On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gelqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. The argument $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

ia (global) INTEGER.
 The row index in the global array A indicating the first row of $\text{sub}(A)$.

ja (global) INTEGER.
 The column index in the global array A indicating the first column of $\text{sub}(A)$.

desca (global and local) INTEGER array of DIMENSION (*dlen_*). The array descriptor for the distributed matrix A .

tau (local)
 REAL for psorml2
 DOUBLE PRECISION for pdorml2
 COMPLEX for pcunml2
 COMPLEX*16 for pzunml2.
 Array, DIMENSION $\text{LOCc}(ia+k-1)$. This array contains the scalar factors τ_{ai} of the elementary reflector $H(i)$, as returned by [p?gelqf](#). This array is tied to the distributed matrix A .

c (local)
 REAL for psorml2
 DOUBLE PRECISION for pdorml2

COMPLEX for `pcunml2`
 COMPLEX*16 for `pzunml2`.
 Pointer into the local memory to an array, `DIMENSION(lld_c, LOCc(jc +n-1))`. On entry, the local pieces of the distributed matrix sub (C).
 ic (global) INTEGER.
 The row index in the global array C indicating the first row of $\text{sub}(C)$.
 jc (global) INTEGER.
 The column index in the global array C indicating the first column of $\text{sub}(C)$.
 $desc_c$ (global and local) INTEGER array of `DIMENSION(dlen_)`. The array descriptor for the distributed matrix C .
 $work$ (local)
 REAL for `psorml2`
 DOUBLE PRECISION for `pdorml2`
 COMPLEX for `pcunml2`
 COMPLEX*16 for `pzunml2`.
 Workspace array, `DIMENSION(lwork)`.
 $lwork$ (local or global) INTEGER.
 The dimension of the array $work$.
 $lwork$ is local input and must be at least
`if side = 'L', lwork ≥ mqc0 + max(max(1, nqc0), numroc(numroc(m+icooffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcm)),`
`if side = 'R', lwork ≥ nqc0 + max(1, mqc0),`
 where
 $lcm = lcm / nprow,$
 $lcm = iclm(nprow, npcol),$
 $iroffc = \text{mod}(ic-1, mb_c),$
 $icooffc = \text{mod}(jc-1, nb_c),$
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow),$
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol),$
 $Mpc0 = \text{numroc}(m+icooffc, mb_c, mycol, icrow, nprow),$
 $Nqc0 = \text{numroc}(n+iroffc, nb_c, myrow, iccol, npcol),$
 $ilcm, \text{indxg2p}$ and `numroc` are ScalAPACK tool functions; $myrow, mycol, nprow, \text{and } npcol$ can be determined by calling the subroutine `blacs_gridinfo`.
 If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

c On exit, c is overwritten by $Q^* \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$

$work$ On exit, $work(1)$ returns the minimal and optimal $lwork$.

$info$ (local) INTEGER.
 = 0: successful exit
 < 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $info = -(i*100+j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

NOTE The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

```
If side = 'L', (nb_a.eq.mb_c .AND. icoffa.eq.iroffc)
If side = 'R', (nb_a.eq.nb_c .AND. icoffa.eq.icoffc .AND. iacol.eq.iccol).
```

p?ormr2/p?unmr2

Multiples a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).

Syntax

```
call psormr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pdormr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pcunmr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)

call pzunmr2(side, trans, m, n, k, a, ia, ja, desca, tau, c, ic, jc, descc, work,
lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?ormr2/p?unmr2 routine overwrites the general real/complex m -by- n distributed matrix sub $(C)=C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^* \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $\text{side} = 'L'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors), or

$\text{sub}(C)^*Q$ if $\text{side} = 'R'$ and $\text{trans} = 'N'$, or

$\text{sub}(C)^*Q^T / \text{sub}(C)^*Q^H$ if $\text{side} = 'R'$ and $\text{trans} = 'T'$ (for real flavors) or $\text{trans} = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1)^*H(2)^*\dots^*H(k)$ (for real flavors)

$Q = (H(1))^H * (H(2))^H * \dots * (H(k))^H$ (for complex flavors)

as returned by p?gerqf. Q is of order m if $\text{side} = 'L'$ and of order n if $\text{side} = 'R'$.

Input Parameters

<i>side</i>	(global) CHARACTER. = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) CHARACTER. = 'N': apply Q (no transpose)

= 'T': apply Q^T (transpose, for real flavors)
= 'C': apply Q^H (conjugate transpose, for complex flavors)

m
(global) INTEGER.
The number of rows to be operated on, that is, the number of rows of the distributed submatrix $\text{sub}(C)$. $m \geq 0$.

n
(global) INTEGER.
The number of columns to be operated on, that is, the number of columns of the distributed submatrix $\text{sub}(C)$. $n \geq 0$.

k
(global) INTEGER.
The number of elementary reflectors whose product defines the matrix Q .
If $\text{side} = 'L'$, $m \geq k \geq 0$;
if $\text{side} = 'R'$, $n \geq k \geq 0$.

a
(local)
REAL for psormr2
DOUBLE PRECISION for pdormr2
COMPLEX for pcunmr2
COMPLEX*16 for pzunmr2.
Pointer into the local memory to an array, DIMENSION
(lld_a , $\text{LOCc}(ja+m-1)$ if $\text{side}='L'$,
 lld_a , $\text{LOCc}(ja+n-1)$ if $\text{side}='R'$,
where $lld_a \geq \max(1, \text{LOCr}(ia+k-1))$.
On entry, the i -th row must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gerqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.
The argument $A(ia:ia+k-1, ja:*)$ is modified by the routine but restored on exit.

ia
(global) INTEGER.
The row index in the global array A indicating the first row of $\text{sub}(A)$.

ja
(global) INTEGER.
The column index in the global array A indicating the first column of $\text{sub}(A)$.

desca
(global and local) INTEGER array of DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .

tau
(local)
REAL for psormr2
DOUBLE PRECISION for pdormr2
COMPLEX for pcunmr2
COMPLEX*16 for pzunmr2.
Array, DIMENSION $\text{LOCc}(ia+k-1)$. This array contains the scalar factors τ_{ai} of the elementary reflector $H(i)$, as returned by [p?gerqf](#). This array is tied to the distributed matrix A .

c
(local)
REAL for psormr2
DOUBLE PRECISION for pdormr2
COMPLEX for pcunmr2
COMPLEX*16 for pzunmr2.
Pointer into the local memory to an array, DIMENSION (lld_c , $\text{LOCc}(jc+n-1)$). On entry, the local pieces of the distributed matrix $\text{sub}(C)$.

ic
(global) INTEGER.
The row index in the global array C indicating the first row of $\text{sub}(C)$.

jc (global) INTEGER.
The column index in the global array *c* indicating the first column of $\text{sub}(C)$.

descC (global and local) INTEGER array of DIMENSION (*dlen_*). The array descriptor for the distributed matrix *C*.

work (local)
REAL for psormr2
DOUBLE PRECISION for pdormr2
COMPLEX for pcunmr2
COMPLEX*16 for pzunmr2.
Workspace array, DIMENSION (*lwork*).

lwork (local or global) INTEGER.
The dimension of the array *work*.
lwork is local input and must be at least

$$\begin{aligned} &\text{if } \text{side} = 'L', \text{lwork} \geq \text{mpc0} + \max(\max(1, \text{nqc0}), \text{numroc}(\text{numroc}(m \\ &+ \text{iroffc}, \text{mb_a}, 0, 0, \text{nprow}), \text{mb_a}, 0, 0, \text{lcmp})), \\ &\text{if } \text{side} = 'R', \text{lwork} \geq \text{nqc0} + \max(1, \text{mpc0}), \\ &\text{where } \text{lcmp} = \text{lcm}/\text{nprow}, \\ &\text{lcm} = \text{iclm}(\text{nprow}, \text{npcol}), \\ &\text{iroffc} = \text{mod}(\text{ic}-1, \text{mb_c}), \\ &\text{icoffc} = \text{mod}(\text{jc}-1, \text{nb_c}), \\ &\text{icrow} = \text{indxg2p}(\text{ic}, \text{mb_c}, \text{myrow}, \text{rsrc_c}, \text{nprow}), \\ &\text{iccol} = \text{indxg2p}(\text{jc}, \text{nb_c}, \text{mycol}, \text{csrc_c}, \text{npcol}), \\ &\text{Mpc0} = \text{numroc}(\text{m}+\text{iroffc}, \text{mb_c}, \text{myrow}, \text{icrow}, \text{nprow}), \\ &\text{Nqc0} = \text{numroc}(\text{n}+\text{icoffc}, \text{nb_c}, \text{mycol}, \text{iccol}, \text{npcol}), \\ &\text{ilcm, indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol,} \\ &\text{nprow, and npcol can be determined by calling the subroutine} \\ &\text{blacs_gridinfo.} \\ &\text{If } \text{lwork} = -1, \text{then lwork is global input and a workspace query is} \\ &\text{assumed; the routine only calculates the minimum and optimal size for all} \\ &\text{work arrays. Each of these values is returned in the first entry of the} \\ &\text{corresponding work array, and no error message is issued by pxerbla.} \end{aligned}$$

Output Parameters

c On exit, *c* is overwritten by $Q^* \text{sub}(C)$, or $Q^T * \text{sub}(C) / Q^H * \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$

work On exit, *work*(1) returns the minimal and optimal *lwork*.

info (local) INTEGER.
= 0: successful exit
< 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
then *info* = - (i*100+j),
if the *i*-th argument is a scalar and had an illegal value,
then *info* = -i.

NOTE The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $\text{side} = 'L'$, ($\text{nb_a.eq.mb_c .AND. icoffa.eq.iroffc}$)
If $\text{side} = 'R'$, ($\text{nb_a.eq.nb_c .AND. icoffa.eq.icoffc .AND. iacol.eq.iccol}$).

p?pbtrs

Solves a single triangular linear system via `frontsolve` or `backsolve` where the triangular matrix is a factor of a banded matrix computed by `p?pbtrf`.

Syntax

```
call pspbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pdpbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pcpbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)

call pzpbtrs(uplo, trans, n, bw, nrhs, a, ja, desca, b, ib, descb, af, laf, work,
lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?pbtrs` routine solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where `A(1:n, ja:ja+n-1)` is a banded triangular matrix factor produced by the Cholesky factorization code `p?pbtrf` and is stored in `A(1:n, ja:ja+n-1)` and `af`. The matrix stored in `A(1:n, ja:ja+n-1)` is either upper or lower triangular according to `uplo`.

Routine `p?pbtrf` must be called first.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Must be ' <code>U</code> ' or ' <code>L</code> '. If <code>uplo</code> = ' <code>U</code> ', upper triangle of <code>A(1:n, ja:ja+n-1)</code> is stored; If <code>uplo</code> = ' <code>L</code> ', lower triangle of <code>A(1:n, ja:ja+n-1)</code> is stored.
<code>trans</code>	(global) CHARACTER. Must be ' <code>N</code> ' or ' <code>T</code> ' or ' <code>C</code> '. If <code>trans</code> = ' <code>N</code> ', solve with <code>A(1:n, ja:ja+n-1)</code> ; If <code>trans</code> = ' <code>T</code> ' or ' <code>C</code> ' for real flavors, solve with <code>A(1:n, ja:ja+n-1)^T</code> . If <code>trans</code> = ' <code>C</code> ' for complex flavors, solve with conjugate transpose <code>(A(1:n, ja:ja+n-1))^H</code> .
<code>n</code>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix <code>A(1:n, ja:ja+n-1)</code> . $n \geq 0$.
<code>bw</code>	(global) INTEGER. The number of subdiagonals in ' <code>L</code> ' or ' <code>U</code> ', $0 \leq bw \leq n-1$.
<code>nrhs</code>	(global) INTEGER.

The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.

a

(local)

REAL for pspbtrs
 DOUBLE PRECISION for pdpbtrs
 COMPLEX for pcpbtrs
 COMPLEX*16 for pzpbtrs.

Pointer into the local memory to an array with the first DIMENSION $lld_a \geq (bw+1)$, stored in *desca*.

On entry, this array contains the local pieces of the n -by- n symmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$.

This local portion is stored in the packed banded format used in LAPACK. See the *Application Notes* below and the ScaLAPACK manual for more detail on the format of distributed matrices.

ja

(global) INTEGER. The index in the global array *A* that points to the start of the matrix to be operated on (which may be either all of *A* or a submatrix of *A*).

desca

(global and local) INTEGER array, DIMENSION (*dlen*). The array descriptor for the distributed matrix *A*.

If 1D type (*dtype_a* = 501), then *dlen* ≥ 7 ;

If 2D type (*dtype_a* = 1), then *dlen* ≥ 9 .

Contains information on mapping of *A* to memory. (See ScaLAPACK manual for full description and options.)

b

(local)

REAL for pspbtrs
 DOUBLE PRECISION for pdpbtrs
 COMPLEX for pcpbtrs
 COMPLEX*16 for pzpbtrs.

Pointer into the local memory to an array of local lead DIMENSION $lld_b \geq nb$.

On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.

ib

(global) INTEGER. The row index in the global array *B* that points to the first row of the matrix to be operated on (which may be either all of *B* or a submatrix of *B*).

descb

(global and local) INTEGER array, DIMENSION (*dlen*). The array descriptor for the distributed matrix *B*.

If 1D type (*dtype_b* = 502), then *dlen* ≥ 7 ;

If 2D type (*dtype_b* = 1), then *dlen* ≥ 9 .

Contains information on mapping of *B* to memory. Please, see ScaLAPACK manual for full description and options.

laf

(local)

INTEGER. The size of user-input auxiliary Fillin space *af*. Must be *laf* $\geq (nb+2*bw) * bw$. If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*(1).

work

(local)

REAL for pspbtrs
 DOUBLE PRECISION for pdpbtrs
 COMPLEX for pcpbtrs
 COMPLEX*16 for pzpbtrs.

	The array <code>work</code> is a temporary workspace array of DIMENSION <code>lwork</code> . This space may be overwritten in between calls to routines.
<code>lwork</code>	(local or global) INTEGER. The size of the user-input workspace <code>work</code> , must be at least $lwork \geq bw * nrhs$. If <code>lwork</code> is too small, the minimal acceptable size will be returned in <code>work(1)</code> and an error code is returned.

Output Parameters

<code>af</code>	(local) REAL for <code>pspbtrs</code> DOUBLE PRECISION for <code>pdpbtrs</code> COMPLEX for <code>pcpbtrs</code> COMPLEX*16 for <code>pzpbtrs</code> .
	The array <code>af</code> is of DIMENSION <code>laf</code> . It contains auxiliary Fillin space. Fillin is created during the factorization routine <code>p?pbtrf</code> and this is stored in <code>af</code> . If a linear system is to be solved using <code>p?pbtrs</code> after the factorization routine, <code>af</code> must not be altered after the factorization.
<code>b</code>	On exit, this array contains the local piece of the solutions distributed matrix <code>x</code> .
<code>work(1)</code>	On exit, <code>work(1)</code> contains the minimum value of <code>lwork</code> .
<code>info</code>	(local) INTEGER. = 0: successful exit < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info = -(i*100+j)</code> , if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

Application Notes

If the factorization routine and the solve routine are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space `af` must not be altered between calls to the factorization routine and the solve routine.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case $N/P \gg bw$ are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix `A` one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into `P` pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

1. **Local Phase:** The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space `af`. Mathematically, this is equivalent to reordering the matrix `A` as PAP^T and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of `A` in memory.
2. **Reduced System Phase:** A small ($bw * (P-1)$) system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space `af`. A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
3. **Back Substitution Phase:** For a linear system, a local backsubstitution is performed on each processor in parallel.

p?pttrsV

Solves a single triangular linear system via `frontsolve` or `backsolve` where the triangular matrix is a factor of a tridiagonal matrix computed by `p?pttrf`.

Syntax

```
call pspttrsV(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pdpttrsV(uplo, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pcpttrsV(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
call pzpttrsV(uplo, trans, n, nrhs, d, e, ja, desca, b, ib, descb, af, laf, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?pttrsV` routine solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:rhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:rhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:rhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a tridiagonal triangular matrix factor produced by the Cholesky factorization code `p?pttrf` and is stored in $A(1:n, ja:ja+n-1)$ and `af`. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`.

Routine `p?pttrf` must be called first.

Input Parameters

<code>uplo</code>	(global) CHARACTER. Must be 'U' or 'L'. If <code>uplo</code> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <code>uplo</code> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<code>trans</code>	(global) CHARACTER. Must be 'N' or 'C'. If <code>trans</code> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <code>trans</code> = 'C' (for complex flavors), solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.
<code>n</code>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.
<code>rhs</code>	(global) INTEGER. The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:rhs)$; $rhs \geq 0$.
<code>d</code>	(local) REAL for <code>pspttrsV</code>

	DOUBLE PRECISION for pdptt _{RSV} COMPLEX for pcptt _{RSV} COMPLEX*16 for pzptt _{RSV} .
	Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq \text{desca}(\text{nb}_\perp)$.
<i>e</i>	(local) REAL for psptt _{RSV} DOUBLE PRECISION for pdptt _{RSV} COMPLEX for pcptt _{RSV} COMPLEX*16 for pzptt _{RSV} . Pointer to the local part of the global vector storing the upper diagonal of the matrix; must be of size $\geq \text{desca}(\text{nb}_\perp)$. Globally, $\text{du}(n)$ is not referenced, and du must be aligned with d .
<i>ja</i>	(global) INTEGER. The index in the global array <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) INTEGER array, DIMENSION (<i>dlen</i>). The array descriptor for the distributed matrix <i>A</i> . If 1D type (<i>dtype_a</i> = 501 or 502), then <i>dlen</i> ≥ 7 ; If 2D type (<i>dtype_a</i> = 1), then <i>dlen</i> ≥ 9 . Contains information on mapping of <i>A</i> to memory. See ScaLAPACK manual for full description and options.
<i>b</i>	(local) REAL for psptt _{RSV} DOUBLE PRECISION for pdptt _{RSV} COMPLEX for pcptt _{RSV} COMPLEX*16 for pzptt _{RSV} . Pointer into the local memory to an array of local lead DIMENSION <i>l1d_b</i> $\geq \text{nb}_\perp$. On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.
<i>ib</i>	(global) INTEGER. The row index in the global array <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) INTEGER array, DIMENSION (<i>dlen</i>). The array descriptor for the distributed matrix <i>B</i> . If 1D type (<i>dtype_b</i> = 502), then <i>dlen</i> ≥ 7 ; If 2D type (<i>dtype_b</i> = 1), then <i>dlen</i> ≥ 9 . Contains information on mapping of <i>B</i> to memory. See ScaLAPACK manual for full description and options.
<i>laf</i>	(local) INTEGER. The size of user-input auxiliary Fillin space <i>af</i> . Must be <i>laf</i> $\geq (\text{nb}+2 * \text{bw}) * \text{bw}$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af(1)</i> .
<i>work</i>	(local) REAL for psptt _{RSV} DOUBLE PRECISION for pdptt _{RSV} COMPLEX for pcptt _{RSV} COMPLEX*16 for pzptt _{RSV} .

The array *work* is a temporary workspace array of DIMENSION *lwork*. This space may be overwritten in between calls to routines.

lwork (local or global) INTEGER. The size of the user-input workspace *work*, must be at least $lwork \geq (10 + 2 * \min(100, nrhs)) * npcol + 4 * nrhs$. If *lwork* is too small, the minimal acceptable size will be returned in *work(1)* and an error code is returned.

Output Parameters

d, e (local).
 REAL for pspttrsv
 DOUBLE PRECISION for pdpttrsv
 COMPLEX for pcpttrsv
 COMPLEX*16 for pzpttrsv.
 On exit, these arrays contain information on the factors of the matrix.

af (local)
 REAL for pspttrsv
 DOUBLE PRECISION for pdpttrsv
 COMPLEX for pcpttrsv
 COMPLEX*16 for pzpttrsv.
 The array *af* is of DIMENSION *laf*. It contains auxiliary Fillin space. Fillin is created during the factorization routine [p?pbtrf](#) and this is stored in *af*. If a linear system is to be solved using [p?pttrs](#) after the factorization routine, *af* must not be altered after the factorization.

b On exit, this array contains the local piece of the solutions distributed matrix *X*.

work(1) On exit, *work(1)* contains the minimum value of *lwork*.

info (local) INTEGER.
 = 0: successful exit
 < 0: if the *i*-th argument is an array and the *j*-entry had an illegal value,
 then *info* = -(*i**100+*j*),
 if the *i*-th argument is a scalar and had an illegal value,
 then *info* = -*i*.

p?potf2

Computes the Cholesky factorization of a symmetric/
 Hermitian positive definite matrix (local unblocked
 algorithm).

Syntax

```
call pspotf2(uplo, n, a, ia, ja, desca, info)
call pdpotf2(uplo, n, a, ia, ja, desca, info)
call pcpotf2(uplo, n, a, ia, ja, desca, info)
call pzpotf2(uplo, n, a, ia, ja, desca, info)
```

Include Files

- C: mkl_scalapack.h

Description

The `p?potf2` routine computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(\text{ia} : \text{ia} + n - 1, \text{ja} : \text{ja} + n - 1)$.

The factorization has the form

$\text{sub}(A) = U^*U$, if $\text{uplo} = 'U'$, or $\text{sub}(A) = L*L'$, if $\text{uplo} = 'L'$,

where U is an upper triangular matrix, L is lower triangular. x^* denotes transpose (conjugate transpose) of x .

Input Parameters

<code>uplo</code>	(global) CHARACTER. Specifies whether the upper or lower triangular part of the symmetric/ Hermitian matrix A is stored. = ' <code>U</code> ': upper triangle of $\text{sub}(A)$ is stored; = ' <code>L</code> ': lower triangle of $\text{sub}(A)$ is stored.
<code>n</code>	(global) INTEGER. The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<code>a</code>	(local) REAL for <code>pspotf2</code> DOUBLE PRECISION or <code>pdpotf2</code> COMPLEX for <code>pcpotf2</code> COMPLEX*16 for <code>pzpotf2</code> . Pointer into the local memory to an array of <code>DIMENSION(lld_a, LOCc(ja +n-1))</code> containing the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$ to be factored. If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced. If $\text{uplo} = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the global array A indicating the first row and the first column of the $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) INTEGER array, <code>DIMENSION(dlen_)</code> . The array descriptor for the distributed matrix A .

Output Parameters

<code>a</code>	(local) On exit, if $\text{uplo} = 'U'$, the upper triangular part of the distributed matrix contains the Cholesky factor U ; if $\text{uplo} = 'L'$, the lower triangular part of the distributed matrix contains the Cholesky factor L .
<code>info</code>	(local) INTEGER. = 0: successful exit < 0: if the i -th argument is an array and the j -entry had an illegal value, then $\text{info} = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $\text{info} = -i$.

> 0 : if $\text{info} = k$, the leading minor of order k is not positive definite, and the factorization could not be completed.

p?rscl

Multiples a vector by the reciprocal of a real scalar.

Syntax

```
call psrscl(n, sa, sx, ix, jx, descx, incx)
call pdrscl(n, sa, sx, ix, jx, descx, incx)
call pcsrcscl(n, sa, sx, ix, jx, descx, incx)
call pzdrscl(n, sa, sx, ix, jx, descx, incx)
```

Include Files

- C: mkl_scalapack.h

Description

The p?rscl routine multiplies an n -element real/complex vector $\text{sub}(x)$ by the real scalar $1/a$. This is done without overflow or underflow as long as the final result $\text{sub}(x)/a$ does not overflow or underflow.

$\text{sub}(x)$ denotes $x(ix:ix+n-1, jx:jx)$, if $\text{incx} = 1$,

and $x(ix:ix, jx:jx+n-1)$, if $\text{incx} = m_x$.

Input Parameters

n	(global) INTEGER. The number of components of the distributed vector $\text{sub}(x)$. $n \geq 0$.
sa	REAL for psrscl/pcsrcscl DOUBLE PRECISION for pdrscl/pzdrscl. The scalar a that is used to divide each component of the vector x . This parameter must be ≥ 0 .
sx	REAL for psrscl DOUBLE PRECISION for pdrscl COMPLEX for pcsrcscl COMPLEX*16 for pzdrscl. Array containing the local pieces of a distributed matrix of DIMENSION of at least $((jx-1)*m_x + ix + (n-1)*\text{abs}(incx))$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix	(global) INTEGER. The row index of the submatrix of the distributed matrix x to operate on.
jx	(global) INTEGER. The column index of the submatrix of the distributed matrix x to operate on.
$descx$	(global and local). INTEGER. Array of DIMENSION 9. The array descriptor for the distributed matrix x .
$incx$	(global) INTEGER. The increment for the elements of x . This version supports only two values of $incx$, namely 1 and m_x .

Output Parameters

<i>sx</i>	On exit, the result x/a .
-----------	-----------------------------

p?sygs2/p?hegs2

Reduces a symmetric/Hermitian definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).

Syntax

```
call pssygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pdsygs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pchechs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
call pzhegs2(ibtype, uplo, n, a, ia, ja, desca, b, ib, jb, descb, info)
```

Include Files

- C:\mkl_scalapack.h

Description

The p?sygs2/p?hegs2 routine reduces a real symmetric-definite or a complex Hermitian-definite generalized eigenproblem to standard form.

Here $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$, and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and $\text{sub}(A)$ is overwritten by

$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ - for real flavors, and

$\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ - for complex flavors.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A) * \text{sub}(B) x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) x = \lambda * x$$

and $\text{sub}(A)$ is overwritten by

$U^* \text{sub}(A) * U^T$ or $L^* * T^* \text{sub}(A) * L$ - for real flavors and

$U^* \text{sub}(A) * U^H$ or $L^* * H^* \text{sub}(A) * L$ - for complex flavors.

The matrix $\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L^* L^T$ (for real flavors), or as $U^H * U$ or $L^* L^H$ (for complex flavors) by p?potrf.

Input Parameters

<i>ibtype</i>	(global) INTEGER. = 1: compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ for real subroutines, and $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ for complex subroutines; = 2 or 3: compute $U^* \text{sub}(A) * U^T$, or $L^T * \text{sub}(A) * L$ for real subroutines,
---------------	---

and $U^* \text{sub}(A) * U^H$ or $L^H * \text{sub}(A) * L$ for complex subroutines.

uplo

(global) CHARACTER

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored, and how $\text{sub}(B)$ is factorized.

= 'U': Upper triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $U^T * U$ (for real subroutines) or as $U^H * U$ (for complex subroutines).

= 'L': Lower triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $L * L^T$ (for real subroutines) or as $L * L^H$ (for complex subroutines)

n

(global) INTEGER.

The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$. $n \geq 0$.

a

(local)

REAL for pssygs2

DOUBLE PRECISION for pdsygs2

COMPLEX for pchegs2

COMPLEX*16 for pzhegs2.

Pointer into the local memory to an array, DIMENSION(*lld_a*, *LOCc(ja+n-1)*).

On entry, this array contains the local pieces of the *n*-by-*n* symmetric/Hermitian distributed matrix $\text{sub}(A)$.

If *uplo* = 'U', the leading *n*-by-*n* upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If *uplo* = 'L', the leading *n*-by-*n* lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER.

The row and column indices in the global array *A* indicating the first row and the first column of the $\text{sub}(A)$, respectively.

desca

(global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *A*.

B

(local)

REAL for pssygs2

DOUBLE PRECISION for pdsygs2

COMPLEX for pchegs2

COMPLEX*16 for pzhegs2.

Pointer into the local memory to an array, DIMENSION(*lld_b*, *LOCc(jb+n-1)*).

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by [p?potrf](#).

ib, jb

(global) INTEGER.

The row and column indices in the global array *B* indicating the first row and the first column of the $\text{sub}(B)$, respectively.

descb

(global and local) INTEGER array, DIMENSION (*dlen_*). The array descriptor for the distributed matrix *B*.

Output Parameters

a

(local)

On exit, if *info* = 0, the transformed matrix is stored in the same format as $\text{sub}(A)$.

info

INTEGER.

= 0: successful exit.
 < 0: if the i -th argument is an array and the j -entry had an illegal value,
 then $\text{info} = - (i * 100)$,
 if the i -th argument is a scalar and had an illegal value,
 then $\text{info} = -i$.

p?sytd2/p?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).

Syntax

```
call pssytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pdsytd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pcheted2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
call pzhetd2(uplo, n, a, ia, ja, desca, d, e, tau, work, lwork, info)
```

Include Files

- C: mkl_scalapack.h

Description

The p?sytd2/p?hetd2 routine reduces a real symmetric/complex Hermitian matrix $\text{sub}(A)$ to symmetric/Hermitian tridiagonal form T by an orthogonal/unitary similarity transformation:

$$Q'^* \text{sub}(A) * Q = T, \text{ where } \text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1).$$

Input Parameters

uplo (global) CHARACTER.
 Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored:
 = 'U': upper triangular
 = 'L': lower triangular

n (global) INTEGER.
 The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.

a (local)
 REAL for pssytd2
 DOUBLE PRECISION for pdsytd2
 COMPLEX for pcheted2
 COMPLEX*16 for pzhetd2.
 Pointer into the local memory to an array, DIMENSION(lld_a, LOCl(ja + n - 1)).
 On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$.
 If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER.

The row and column indices in the global array A indicating the first row and the first column of the $\text{sub}(A)$, respectively.

$desca$

(global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .

$work$

(local)

REAL for pssytd2

DOUBLE PRECISION for pdsytd2

COMPLEX for pchetd2

COMPLEX*16 for pzhetd2.

The array $work$ is a temporary workspace array of DIMENSION $lwork$.

Output Parameters

a

On exit, if $uplo = 'U'$, the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors; if $uplo = 'L'$, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array tau , represent the orthogonal/unitary matrix Q as a product of elementary reflectors. See the *Application Notes* below.

d

(local)

REAL for pssytd2/pchetd2

DOUBLE PRECISION for pdsytd2/pzhetd2.

Array, DIMENSION ($LOCc(ja+n-1)$). The diagonal elements of the tridiagonal matrix T :

$d(i) = a(i,i)$; d is tied to the distributed matrix A .

e

(local)

REAL for pssytd2/pchetd2

DOUBLE PRECISION for pdsytd2/pzhetd2.

Array, DIMENSION ($LOCc(ja+n-1)$),

if $uplo = 'U'$, $LOCc(ja+n-2)$ otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$e(i) = a(i,i+1)$ if $uplo = 'U'$,

$e(i) = a(i+1,i)$ if $uplo = 'L'$.

e is tied to the distributed matrix A .

tau

(local)

REAL for pssytd2

DOUBLE PRECISION for pdsytd2

COMPLEX for pchetd2

COMPLEX*16 for pzhetd2.

Array, DIMENSION ($LOCc(ja+n-1)$).

The scalar factors of the elementary reflectors. tau is tied to the distributed matrix A .

$work(1)$

On exit, $work(1)$ returns the minimal and optimal value of $lwork$.

$lwork$

(local or global) INTEGER.

The dimension of the workspace array `work`.

`lwork` is local input and must be at least $lwork \geq 3n$.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the routine only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

`info` (local) INTEGER.

= 0: successful exit

< 0: if the i -th argument is an array and the j -entry had an illegal value, then `info = -(i*100)`,

if the i -th argument is a scalar and had an illegal value, then `info = -i`.

Application Notes

If `uplo = 'U'`, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v^T,$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and tau in $TAU(ja+i-1)$.

If `uplo = 'L'`, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - tau * v * v^T,$$

where tau is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and tau in $TAU(ja+i-1)$.

The contents of sub (A) on exit are illustrated by the following examples with $n = 5$:

$\text{if } uplo='U':$ $\begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ d & e & v_3 & v_4 & \\ d & e & v_4 & & \\ d & e & & & \\ d & & & & \end{bmatrix}$	$\text{if } uplo='L':$ $\begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix}$
--	--

where d and e denotes diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

NOTE The distributed submatrix `sub(A)` must verify some alignment properties, namely the following expression should be true:

(`mb_a.eq.nb_a .AND. iroffa.eq.icoffa`) with `iroffa = mod(ia - 1, mb_a)` and `icoffa = mod(ja - 1, nb_a)`.

p?trti2

Computes the inverse of a triangular matrix (local unblocked algorithm).

Syntax

```

call pstrti2(uplo, diag, n, a, ia, ja, desca, info)
call pdtrti2(uplo, diag, n, a, ia, ja, desca, info)
call pctrti2(uplo, diag, n, a, ia, ja, desca, info)
call pztrti2(uplo, diag, n, a, ia, ja, desca, info)

```

Include Files

- C: mkl scalapack.h

Description

The p?trti2 routine computes the inverse of a real/complex upper or lower triangular block matrix sub (A) = $A(ia:ia+n-1, ja:ja+n-1)$.

This matrix should be contained in one and only one process memory space (local operation).

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the matrix sub (A) is upper or lower triangular. = 'U': sub (A) is upper triangular = 'L': sub (A) is lower triangular.
<i>diag</i>	(global) CHARACTER*1. Specifies whether or not the matrix A is unit triangular. = 'N': sub (A) is non-unit triangular = 'U': sub (A) is unit triangular.
<i>n</i>	(global) INTEGER. The number of rows and columns to be operated on, i.e., the order of the distributed submatrix sub (A). $n \geq 0$.
<i>a</i>	(local) REAL for pstrti2 DOUBLE PRECISION for pdtrti2 COMPLEX for pctrti2 COMPLEX*16 for pztrti2. Pointer into the local memory to an array, DIMENSION(11 <i>d_a</i> , LOCc(<i>ja</i> + <i>n</i> -1)). On entry, this array contains the local pieces of the triangular matrix sub(A). If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the matrix sub(A) contains the upper triangular part of the matrix, and the strictly lower triangular part of sub(A) is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the matrix sub(A) contains the lower triangular part of the matrix, and the strictly upper triangular part of sub(A) is not referenced. If <i>diag</i> = 'U', the diagonal elements of sub(A) are not referenced either and are assumed to be 1.
<i>ia</i> , <i>ja</i>	(global) INTEGER.

The row and column indices in the global array A indicating the first row and the first column of the sub(A), respectively.

$desca$ (global and local) INTEGER array, DIMENSION ($dlen_$). The array descriptor for the distributed matrix A .

Output Parameters

a On exit, the (triangular) inverse of the original matrix, in the same storage format.

$info$ INTEGER.
 $= 0$: successful exit
 < 0 : if the i -th argument is an array and the j -entry had an illegal value, then $info = - (i*100)$,
if the i -th argument is a scalar and had an illegal value, then $info = -i$.

?lamsh

Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.

Syntax

```
call slamsh(s, lds, nbudge, jblk, h, ldh, n, ulp)
call dlamsh(s, lds, nbudge, jblk, h, ldh, n, ulp)
```

Include Files

- C: mkl_scalapack.h

Description

The ?lamsh routine sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The subroutine should only be called when there are multiple shifts/bulges ($nbudge > 1$) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

Input Parameters

s (local)
INTEGER. REAL for slamsh
DOUBLE PRECISION for dlamsh
Array, DIMENSION ($lds,*$).
On entry, the matrix of shifts. Only the 2×2 diagonal of s is referenced. It is assumed that s has $jblk$ double shifts (size 2).

lds (local) INTEGER.
On entry, the leading dimension of s ; unchanged on exit. $1 < nbudge \leq jblk \leq lds/2$.

$nbudge$ (local) INTEGER.
On entry, the number of bulges to send through h (>1). $nbudge$ should be less than the maximum determined ($jblk$). $1 < nbudge \leq jblk \leq lds/2$.

$jblk$ (local) INTEGER.

	On entry, the leading dimension of s ; unchanged on exit.
h	(local) INTEGER. REAL for slamsh DOUBLE PRECISION for dlamsh Array, DIMENSION (lds, n). On entry, the local matrix to apply the shifts on. h should be aligned so that the starting row is 2.
ldh	(local) INTEGER. On entry, the leading dimension of H ; unchanged on exit.
n	(local) INTEGER. On entry, the size of H . If all the bulges are expected to go through, n should be at least $4nbulge+2$. Otherwise, $nbulge$ may be reduced by this routine.
ulp	(local) REAL for slamsh DOUBLE PRECISION for dlamsh On entry, machine precision. Unchanged on exit.

Output Parameters

s	On exit, the data is rearranged in the best order for applying.
$nbulge$	On exit, the maximum number of bulges that can be sent through.
h	On exit, the data is destroyed.

?laref

Applies Householder reflectors to matrices on either their rows or columns.

Syntax

```
call slaref(type, a, lda, wantz, z, ldz, block, irow1, icoll, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3)
call dlaref(type, a, lda, wantz, z, ldz, block, irow1, icoll, istart, istop, itmp1,
itmp2, liloz, lihiz, vecs, v2, v3, t1, t2, t3)
```

Include Files

- C: mkl_scalapack.h

Description

The ?laref routine applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

$type$	(global) CHARACTER*1. If $type = 'R'$, apply reflectors to the rows of the matrix (apply from left). Otherwise, apply reflectors to the columns of the matrix. Unchanged on exit.
a	(global) REAL for slaref DOUBLE PRECISION for dlaref

Array, DIMENSION (*lda*, *).
 On entry, the matrix to receive the reflections.

lda
 (local) INTEGER.
 On entry, the leading dimension of *A*; unchanged on exit.

wantz
 (global) LOGICAL.
 If *wantz* = .TRUE., apply any column reflections to *Z* as well.
 If *wantz* = .FALSE., do no additional work on *Z*.

z
 (global) REAL for slaref
 DOUBLE PRECISION for dlaref
 Array, DIMENSION (*ldz*, *).
 On entry, the second matrix to receive column reflections.

ldz
 (local) INTEGER.
 On entry, the leading dimension of *Z*; unchanged on exit.

block
 (global). LOGICAL.
 = .TRUE. : apply several reflectors at once and read their data from the *vecs* array;
 = .FALSE. : apply the single reflector given by *v2*, *v3*, *t1*, *t2*, and *t3*.

irow1
 (local) INTEGER.
 On entry, the local row element of the matrix *A*.

icoll
 (local) INTEGER.
 On entry, the local column element of the matrix *A*.

istart
 (global) INTEGER.
 Specifies the "number" of the first reflector.
istart is used as an index into *vecs* if *block* is set. *istart* is ignored if *block* is .FALSE..

istop
 (global) INTEGER.
 Specifies the "number" of the last reflector.
istop is used as an index into *vecs* if *block* is set. *istop* is ignored if *block* is .FALSE..

itmp1
 (local) INTEGER.
 Starting range into *A*. For rows, this is the local first column. For columns, this is the local first row.

itmp2
 (local) INTEGER.
 Ending range into *A*. For rows, this is the local last column. For columns, this is the local last row.

liloz, lihiz
 (local). INTEGER.
 Serve the same purpose as *itmp1*, *itmp2* but for *Z* when *wantz* is set.

vecs
 (global)
 REAL for slaref
 DOUBLE PRECISION for dlaref.
 Array of size $3 * n$ (matrix size). This array holds the size 3 reflectors one after another and is only accessed when *block* is .TRUE..

v2,v3,t1,t2,t3
 (global). INTEGER.
 REAL for slaref
 DOUBLE PRECISION for dlaref.
 These parameters hold information on a single size 3 Householder reflector and are read when *block* is .FALSE., and overwritten when *block* is .TRUE..

Output Parameters

<i>a</i>	On exit, the updated matrix.
<i>z</i>	Changed only if <i>wantz</i> is set. If <i>wantz</i> is .FALSE., <i>z</i> is not referenced.
<i>irow1</i>	Undefined.
<i>icoll</i>	Undefined.
<i>v2,v3,t1,t2,t3</i>	These parameters are read when <i>block</i> is .FALSE., and overwritten when <i>block</i> is .TRUE..

?lasorte

Sorts eigenpairs by real and complex data types.

Syntax

```
call slasorte(s, lds, j, out, info)
call dlasorte(s, lds, j, out, info)
```

Include Files

- C: mkl_scalapack.h

Description

The ?lasorte routine sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This routine does no parallel work and makes no calls.

Input Parameters

<i>s</i>	(local) INTEGER. REAL for slasorte DOUBLE PRECISION for dlasorte Array, DIMENSION (<i>lds</i>). On entry, a matrix already in Schur form.
<i>lds</i>	(local) INTEGER. On entry, the leading dimension of the array <i>s</i> ; unchanged on exit.
<i>j</i>	(local) INTEGER. On entry, the order of the matrix <i>s</i> ; unchanged on exit.
<i>out</i>	(local) INTEGER. REAL for slasorte DOUBLE PRECISION for dlasorte Array, DIMENSION (2*j). The work buffer required by the routine.
<i>info</i>	(local) INTEGER. Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix <i>s</i> was not originally in Schur form. 0 indicates successful completion.

Output Parameters

<i>s</i>	On exit, the diagonal blocks of <i>s</i> have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.
<i>out</i>	Work buffer.

?lasrt2

Sorts numbers in increasing or decreasing order.

Syntax

```
call slasrt2(id, n, d, key, info)
call dlasrt2(id, n, d, key, info)
```

Include Files

- C: mkl_scalapack.h

Description

The ?lasrt2 routine is modified LAPACK routine ?lasrt, which sorts the numbers in d in increasing order (if $id = 'I'$) or in decreasing order (if $id = 'D'$). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of STACK limits n to about 2^{32} .

Input Parameters

<i>id</i>	CHARACTER*1. = 'I': sort d in increasing order; = 'D': sort d in decreasing order.
<i>n</i>	INTEGER. The length of the array d .
<i>d</i>	REAL for slasrt2 DOUBLE PRECISION for dlasrt2. Array, DIMENSION (n). On entry, the array to be sorted.
<i>key</i>	INTEGER. Array, DIMENSION (n). On entry, <i>key</i> contains a key to each of the entries in $d()$. Typically, $key(i) = i$ for all i .

Output Parameters

<i>D</i>	On exit, d has been sorted into increasing order ($d(1) \leq \dots \leq d(n)$) or into decreasing order ($d(1) \geq \dots \geq d(n)$), depending on <i>id</i> .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = $-i$, the i -th argument had an illegal value.
<i>key</i>	On exit, <i>key</i> is permuted in exactly the same manner as $d()$ was permuted from input to output. Therefore, if $key(i) = i$ for all i upon input, then $d_{\text{out}}(i) = d_{\text{in}}(key(i))$.

?stein2

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.

Syntax

```
call sstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail, info)
```

```
call dstein2(n, d, e, m, w, iblock, isplit, orfac, z, ldz, work, iwork, ifail, info)
```

Include Files

- C: mkl_scalapack.h

Description

The `?stein2` routine is a modified LAPACK routine `?stein`. It computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter `maxits` (currently set to 5).

Input Parameters

<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>m</i>	INTEGER. The number of eigenvectors to be found ($0 \leq m \leq n$).
<i>d</i> , <i>e</i> , <i>w</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*), DIMENSION (<i>n</i>). The <i>n</i> diagonal elements of the tridiagonal matrix T . <i>e</i> (*), DIMENSION (<i>n</i>). The (<i>n</i> -1) subdiagonal elements of the tridiagonal matrix T , in elements 1 to <i>n</i> -1. <i>e</i> (<i>n</i>) need not be set. <i>w</i> (*), DIMENSION (<i>n</i>). The first <i>m</i> elements of <i>w</i> contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array <i>w</i> from <code>?stebz</code> with ORDER = 'B' is expected here). The dimension of <i>w</i> must be at least <code>max(1, n)</code> .
<i>iblock</i>	INTEGER. Array, DIMENSION (<i>n</i>). The submatrix indices associated with the corresponding eigenvalues in <i>w</i> ; <i>iblock</i> (<i>i</i>) = 1, if eigenvalue <i>w</i> (<i>i</i>) belongs to the first submatrix from the top, <i>iblock</i> (<i>i</i>) = 2, if eigenvalue <i>w</i> (<i>i</i>) belongs to the second submatrix, etc. (The output array <i>iblock</i> from <code>?stebz</code> is expected here).
<i>isplit</i>	INTEGER. Array, DIMENSION (<i>n</i>). The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> (1), the second submatrix consists of rows/columns <i>isplit</i> (1)+1 through <i>isplit</i> (2), etc. (The output array <i>isplit</i> from <code>?stebz</code> is expected here).
<i>orfac</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>orfac</i> specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within <i>orfac</i> * T of each other are to be orthogonalized.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> ; <i>ldz</i> $\geq \max(1, n)$.
<i>work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Workspace array, DIMENSION (5 <i>n</i>).

iwork INTEGER. Workspace array, DIMENSION (*n*).

Output Parameters

z REAL for sstein2
 DOUBLE PRECISION for dstein2
 Array, DIMENSION (*ldz*, *m*).
 The computed eigenvectors. The eigenvector associated with the eigenvalue $w(i)$ is stored in the *i*-th column of *z*. Any vector that fails to converge is set to its current iterate after *maxits* iterations.

ifail INTEGER.
 Array, DIMENSION (*m*).
 On normal exit, all elements of *ifail* are zero. If one or more eigenvectors fail to converge after *maxits* iterations, then their indices are stored in the array *ifail*.

info INTEGER.
info = 0, if the exit is successful.
info < 0: if *info* = *-i*, the *i*-th had an illegal value.
info > 0: if *info* = *i*, then *i* eigenvectors failed to converge in *maxits* iterations. Their indices are stored in the array *ifail*.

?dbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Syntax

```
call sdbtf2(m, n, k1, ku, ab, ldab, info)
call ddbtf2(m, n, k1, ku, ab, ldab, info)
call cdbtf2(m, n, k1, ku, ab, ldab, info)
call zdbtf2(m, n, k1, ku, ab, ldab, info)
```

Include Files

- C: mkl_scalapack.h

Description

The ?dbtf2 routine computes an LU factorization of a general real/complex *m*-by-*n* band matrix *A* without using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

m INTEGER. The number of rows of the matrix *A* (*m* \geq 0).
n INTEGER. The number of columns in *A* (*n* \geq 0).
k1 INTEGER. The number of sub-diagonals within the band of *A* (*k1* \geq 0).
ku INTEGER. The number of super-diagonals within the band of *A* (*ku* \geq 0).
ab REAL for sdbtf2
 DOUBLE PRECISION for ddbtf2
 COMPLEX for cdbtf2

`COMPLEX*16` for `zdbtf2`.

`Array`, `DIMENSION (ldab, n)`.

The matrix `A` in band storage, in rows k_1+1 to $2k_1+ku+1$; rows 1 to k_1 of the array need not be set. The j -th column of `A` is stored in the j -th column of the array `ab` as follows: $ab(k_1+ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+k_1)$.

`ldab`

`INTEGER`. The leading dimension of the array `ab`.

$(ldab \geq 2k_1 + ku + 1)$

Output Parameters

`ab`

On exit, details of the factorization: `U` is stored as an upper triangular band matrix with k_1+ku superdiagonals in rows 1 to k_1+ku+1 , and the multipliers used during the factorization are stored in rows k_1+ku+2 to $2*k_1+ku+1$. See the *Application Notes* below for further details.

`info`

`INTEGER`.

= 0: successful exit

< 0: if `info = - i`, the i -th argument had an illegal value,

> 0: if `info = + i`, $u(i, i)$ is 0. The factorization has been completed, but the factor `U` is exactly singular. Division by 0 will occur if you use the factor `U` for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $k_1 = 2$, $ku = 1$:

on entry	on exit
$\begin{bmatrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$	$\begin{bmatrix} * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{bmatrix}$

The routine does not use array elements marked *; elements marked + need not be set on entry, but the routine requires them to store elements of `U`, because of fill-in resulting from the row interchanges.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

```

Include Files

- C: `mkl_scalapack.h`

Description

This routine computes an LU factorization of a real m -by- n band matrix A without using partial pivoting or row interchanges.

This is the blocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
k_1	INTEGER. The number of sub-diagonals within the band of A ($k_1 \geq 0$).
k_u	INTEGER. The number of super-diagonals within the band of A ($k_u \geq 0$).
ab	REAL for sdbtrf DOUBLE PRECISION for ddbtrf COMPLEX for cdbtrf COMPLEX*16 for zdbtrf. Array, DIMENSION (l_{dab}, n). The matrix A in band storage, in rows k_1+1 to $2k_1+k_u+1$; rows 1 to k_1 of the array need not be set. The j -th column of A is stored in the j -th column of the array ab as follows: $ab(k_1+k_u+1+i-j, j) = A(i, j)$ for $\max(1, j-k_u) \leq i \leq \min(m, j+k_1)$.
l_{dab}	INTEGER. The leading dimension of the array ab . ($l_{dab} \geq 2k_1 + k_u + 1$)

Output Parameters

ab	On exit, details of the factorization: U is stored as an upper triangular band matrix with k_1+k_u superdiagonals in rows 1 to k_1+k_u+1 , and the multipliers used during the factorization are stored in rows k_1+k_u+2 to $2*k_1+k_u+1$. See the <i>Application Notes</i> below for further details.
$info$	INTEGER. = 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value, > 0: if $info = +i$, $u(i, i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $k_1 = 2$, $k_u = 1$:

$$\begin{array}{c} \text{on entry} \\ \left[\begin{array}{cccccc} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{array} \right] \end{array} \quad \begin{array}{c} \text{on exit} \\ \left[\begin{array}{cccccc} * & u_{12} & u_{23} & u_{34} & u_{45} & u_{56} \\ u_{11} & u_{22} & u_{33} & u_{44} & u_{55} & u_{66} \\ m_{21} & m_{32} & m_{43} & m_{54} & m_{65} & * \\ m_{31} & m_{42} & m_{53} & m_{64} & * & * \end{array} \right] \end{array}$$

The routine does not use array elements marked *.

?dttrf

Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).

Syntax

```
call sdttrf(n, dl, d, du, info)
call ddttrf(n, dl, d, du, info)
call cdttrf(n, dl, d, du, info)
call zdttrf(n, dl, d, du, info)
```

Include Files

- C: mkl_scalapack.h

Description

The ?dttrf routine computes an LU factorization of a real or complex tridiagonal matrix A using elimination without partial pivoting.

The factorization has the form $A = L \cdot U$, where L is a product of unit lower bidiagonal matrices and U is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>dl, d, du</i>	REAL for sdttrf DOUBLE PRECISION for ddttrf COMPLEX for cdttrf COMPLEX*16 for zdttrf. Arrays containing elements of A . The array <i>dl</i> of DIMENSION($n - 1$) contains the sub-diagonal elements of A . The array <i>d</i> of DIMENSION n contains the diagonal elements of A . The array <i>du</i> of DIMENSION($n - 1$) contains the super-diagonal elements of A .

Output Parameters

<i>dl</i>	Overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .
<i>d</i>	Overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A .
<i>du</i>	Overwritten by the $(n-1)$ elements of the first super-diagonal of U .
<i>info</i>	INTEGER. = 0: successful exit < 0: if <i>info</i> = $-i$, the i -th argument had an illegal value, > 0: if <i>info</i> = i , $u(i,i)$ is exactly 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

?dttrsV

Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.

Syntax

```
call sdttrsV(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call ddttrsV(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call cdttrsV(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
call zdttrsV(uplo, trans, n, nrhs, dl, d, du, b, ldb, info)
```

Include Files

- C: mkl_scalapack.h

Description

The ?dttrsV routine solves one of the following systems of linear equations:

$$L^*X = B, L^T*X = B, \text{ or } L^H*X = B,$$

$$U^*X = B, U^T*X = B, \text{ or } U^H*X = B$$

with factors of the tridiagonal matrix A from the LU factorization computed by ?dttrf.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether to solve with L or U .
<i>trans</i>	CHARACTER. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $A^*X=B$ is solved for X (no transpose). If <i>trans</i> = 'T', then $A^T*X = B$ is solved for X (transpose). If <i>trans</i> = 'C', then $A^H*X = B$ is solved for X (conjugate transpose).
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns in the matrix B ($nrhs \geq 0$).
<i>dl,d,du,b</i>	REAL for sdttrsV DOUBLE PRECISION for ddttrsV COMPLEX for cdttrsV COMPLEX*16 for zdttrsV. Arrays of DIMENSIONS: $dl(n - 1), d(n), du(n - 1), b(ldb, nrhs)$. The array <i>dl</i> contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A . The array <i>d</i> contains n diagonal elements of the upper triangular matrix U from the LU factorization of A . The array <i>du</i> contains the $(n - 1)$ elements of the first super-diagonal of U . On entry, the array <i>b</i> contains the right-hand side matrix B .
<i>ldb</i>	INTEGER. The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

?ptttrs

Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the $L^*D^*L^H$ factorization computed by ?pttrf.

Syntax

```
call sptttrs(trans, n, nrhs, d, e, b, ldb, info)
call dptttrs(trans, n, nrhs, d, e, b, ldb, info)
call cptttrs(uplo, trans, n, nrhs, d, e, b, ldb, info)
call zptttrs(uplo, trans, n, nrhs, d, e, b, ldb, info)
```

Include Files

- C: mkl_scalapack.h

Description

The ?ptttrs routine solves one of the triangular systems:

$L^T X = B$, or $L^* X = B$ for real flavors,

or

$L^* X = B$, or $L^H X = B$,

$U^* X = B$, or $U^H X = B$ for complex flavors,

where *L* (or *U* for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix *A* such that

$A = L^* D^* L^H$ (computed by spttrf/dpttrf)

or

$A = U^H D^* U$ or $A = L^* D^* L^H$ (computed by cpttrf/zpttrf).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix <i>A</i> is stored and the form of the factorization: If <i>uplo</i> = 'U', <i>e</i> is the superdiagonal of <i>U</i> , and $A = U^H D^* U$ or $A = L^* D^* L^H$; if <i>uplo</i> = 'L', <i>e</i> is the subdiagonal of <i>L</i> , and $A = L^* D^* L^H$. The two forms are equivalent, if <i>A</i> is real.
<i>trans</i>	CHARACTER. Specifies the form of the system of equations: for real flavors: if <i>trans</i> = 'N': $L^* X = B$ (no transpose) if <i>trans</i> = 'T': $L^T X = B$ (transpose) for complex flavors:

if $\text{trans} = \text{'N'}$: $U*X = B$ or $L*X = B$ (no transpose)
 if $\text{trans} = \text{'C'}$: $U^H*X = B$ or $L^H*X = B$ (conjugate transpose).

n INTEGER. The order of the tridiagonal matrix A . $n \geq 0$.

nrhs INTEGER. The number of right hand sides, that is, the number of columns of the matrix B . $nrhs \geq 0$.

d REAL array, DIMENSION (*n*). The *n* diagonal elements of the diagonal matrix D from the factorization computed by [?pttrf](#).

e COMPLEX array, DIMENSION (*n-1*). The (*n-1*) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by [?pttrf](#).
 See *uplo*.

b COMPLEX array, DIMENSION (*ldb, nrhs*).
 On entry, the right hand side matrix B .

ldb INTEGER.
 The leading dimension of the array *b*.
 $ldb \geq \max(1, n)$.

Output Parameters

b On exit, the solution matrix X .

info INTEGER.
 $= 0$: successful exit
 < 0 : if $\text{info} = -i$, the *i*-th argument had an illegal value.

?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

```
call ssteqr2(compz, n, d, e, z, ldz, nr, work, info)
call dsteqr2(compz, n, d, e, z, ldz, nr, work, info)
```

Include Files

- C: mkl_scalapack.h

Description

The [?steqr2](#) routine is a modified version of LAPACK routine [?steqr](#). The [?steqr2](#) routine computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. [?steqr2](#) is modified from [?steqr](#) to allow each ScaLAPACK process running [?steqr2](#) to perform updates on a distributed matrix Q . Proper usage of [?steqr2](#) can be gleaned from examination of ScaLAPACK routine [p?syev](#).

Input Parameters

compz CHARACTER*1. Must be 'N' or 'I'.
 If $\text{compz} = \text{'N'}$, the routine computes eigenvalues only. If $\text{compz} = \text{'I'}$, the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T .

z must be initialized to the identity matrix by `p?laset` or `?laset` prior to entering this subroutine.

n INTEGER. The order of the matrix T ($n \geq 0$).

$d, e, work$ REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays: d contains the diagonal elements of T . The dimension of d must be at least $\max(1, n)$.

e contains the $(n-1)$ subdiagonal elements of T . The dimension of e must be at least $\max(1, n-1)$.

$work$ is a workspace array. The dimension of $work$ is $\max(1, 2*n-2)$. If $compz = 'N'$, then $work$ is not referenced.

z (local)

REAL for `ssteqr2`

DOUBLE PRECISION for `dsteqr2`

Array, global DIMENSION (n, n), local DIMENSION (ldz, nr).

If $compz = 'V'$, then z contains the orthogonal matrix used in the reduction to tridiagonal form.

ldz INTEGER. The leading dimension of the array z . Constraints:

$ldz \geq 1$,

$ldz \geq \max(1, n)$, if eigenvectors are desired.

nr INTEGER. $nr = \max(1, numroc(n, nb, myprow, 0, nprocs))$.

If $compz = 'N'$, then nr is not referenced.

Output Parameters

d REAL array, DIMENSION (n), for `ssteqr2`.

DOUBLE PRECISION array, DIMENSION (n), for `dsteqr2`.

On exit, the eigenvalues in ascending order, if $info = 0$.

See also $info$.

e REAL array, DIMENSION ($n-1$), for `ssteqr2`.

DOUBLE PRECISION array, DIMENSION ($n-1$), for `dsteqr2`.

On exit, e has been destroyed.

z (local)

REAL for `ssteqr2`

DOUBLE PRECISION for `dsteqr2`

Array, global DIMENSION (n, n), local DIMENSION (ldz, nr).

On exit, if $info = 0$, then,

if $compz = 'V'$, z contains the orthonormal eigenvectors of the original symmetric matrix, and if $compz = 'I'$, z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $compz = 'N'$, then z is not referenced.

$info$ INTEGER.

$info = 0$, the exit is successful.

$info < 0$: if $info = -i$, the i -th had an illegal value.

$info > 0$: the algorithm has failed to find all the eigenvalues in a total of $30n$ iterations;

if $info = i$, then i elements of e have not converged to zero; on exit, d and e contain the elements of a symmetric tridiagonal matrix, which is orthogonally similar to the original matrix.

Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

ScaLAPACK Utility Functions and Routines

Routine Name	Data Types	Description
p?labad	s, d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
p?lachkieee	s, d	Performs a simple check for the features of the IEEE standard. (C interface function).
p?lamch	s, d	Determines machine parameters for floating-point arithmetic.
p?lasnbt	s, d	Computes the position of the sign bit of a floating-point number. (C interface function).
pixerbla		Error handling routine called by ScaLAPACK routines.

p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
call pslabad(ictxt, small, large)
call pdlabad(ictxt, small, large)
```

Include Files

- C: mkl_scalapack.h

Description

The p?labad routine takes as input the values computed by p?lamch for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This subroutine is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by p?lamch. This subroutine is needed because p?lamch does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this routine performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

<i>ictxt</i>	(global) INTEGER. The BLACS context handle in which the computation takes place.
<i>small</i>	(local). REAL PRECISION for pslabad. DOUBLE PRECISION for pdlabad. On entry, the underflow threshold as computed by p?lamch.
<i>large</i>	(local). REAL PRECISION for pslabad. DOUBLE PRECISION for pdlabad.

On entry, the overflow threshold as computed by `p?lamch`.

Output Parameters

<code>small</code>	(local). On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <code>small</code> , otherwise unchanged.
<code>large</code>	(local). On exit, if $\log_{10}(\text{large})$ is sufficiently large, the square root of <code>large</code> , otherwise unchanged.

p?lachkieee

Performs a simple check for the features of the IEEE standard. (C interface function).

Syntax

```
void pslachkieee(int *isieee, float *rmax, float *rmin);
void pdlachkieee(int *isieee, float *rmax, float *rmin);
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lachkieee` routine performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, `p?lachkieee` may not return.

Note that all arguments are call-by-reference so that this routine can be directly called from Fortran code.

This is a ScaLAPACK internal subroutine and arguments are not checked for unreasonable values.

Input Parameters

<code>rmax</code>	(local). REAL for <code>pslachkieee</code> DOUBLE PRECISION for <code>pdlachkieee</code> The overflow threshold (= <code>?lamch ('O')</code>).
<code>rmin</code>	(local). REAL for <code>pslachkieee</code> DOUBLE PRECISION for <code>pdlachkieee</code> The underflow threshold (= <code>?lamch ('U')</code>).

Output Parameters

<code>isieee</code>	(local). INTEGER. On exit, <code>isieee</code> = 1 implies that all the features of the IEEE standard that we rely on are implemented. On exit, <code>isieee</code> = 0 implies that some the features of the IEEE standard that we rely on are missing.
---------------------	---

p?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
val = pslamch(ictxt, cmach)
val = pdlamch(ictxt, cmach)
```

Include Files

- C: mkl_scalapack.h

Description

The p?lamch routine determines single precision machine parameters.

Input Parameters

<i>ictxt</i>	(global). INTEGER. The BLACS context handle in which the computation takes place.
<i>cmach</i>	(global) CHARACTER*1. Specifies the value to be returned by p?lamch: = 'E' or 'e', p?lamch := eps = 'S' or 's', p?lamch := sfmin = 'B' or 'b', p?lamch := base = 'P' or 'p', p?lamch := eps*base = 'N' or 'n', p?lamch := t = 'R' or 'r', p?lamch := rnd = 'M' or 'm', p?lamch := emin = 'U' or 'u', p?lamch := rmin = 'L' or 'l', p?lamch := emax = 'O' or 'o', p?lamch := rmax, where eps = relative machine precision sfmin = safe minimum, such that 1/sfmin does not overflow base = base of the machine prec = eps*base t = number of (base) digits in the mantissa rnd = 1.0 when rounding occurs in addition, 0.0 otherwise emin = minimum exponent before (gradual) underflow rmin = underflow threshold - base ^(emin-1) emax = largest exponent before overflow rmax = overflow threshold - (base ^{emax}) * (1-eps)

Output Parameters

<i>val</i>	Value returned by the routine.
------------	--------------------------------

p?lasnbt

Computes the position of the sign bit of a floating-point number. (C interface function).

Syntax

```
void pslasnbt(int *ieflag);
void pdlasnbt(int *ieflag);
```

Include Files

- C: mkl_scalapack.h

Description

The `p?lasnbt` routine finds the position of the signbit of a single/double precision floating point number. This routine assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

Output Parameters

<code>ieflag</code>	INTEGER. This flag indicates the position of the signbit of any single/double precision floating point number. <code>ieflag = 0</code> , if the compile time flag <code>NO_IEEE</code> indicates that the machine does not have IEEE arithmetic, or if <code>sizeof(int)</code> is different from 4 bytes. <code>ieflag = 1</code> indicates that the signbit is the 32-nd bit for a single precision routine. In the case of a double precision routine: <code>ieflag = 1</code> indicates that the signbit is the 32-nd bit (Big Endian). <code>ieflag = 2</code> indicates that the signbit is the 64-th bit (Little Endian).
---------------------	--

pixerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
call pixerbla(ictxt, srname, info)
```

Include Files

- C: mkl_scalapack.h

Description

This routine is an error handler for the *ScaLAPACK* routines. It is called by a *ScaLAPACK* routine if an input parameter has an invalid value. A message is printed. Program execution is not terminated. For the *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pixerbla`.

Control returns to the higher-level calling routine, and it is left to the user to determine how the program should proceed. However, in the specialized low-level *ScaLAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pixerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of `info` on return from a *ScaLAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Input Parameters

<code>ictxt</code>	(global) INTEGER The BLACS context handle, indicating the global context of the operation. The context itself is global.
<code>srname</code>	(global) CHARACTER*6

The name of the routine which called pxerbla.

info

(global) INTEGER.

The position of the invalid parameter in the parameter list of the calling routine.

Sparse Solver Routines

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparse solver software to solve real or complex, symmetric, structurally symmetric or non-symmetric, positive definite, indefinite or Hermitian sparse linear system of equations.

The terms and concepts required to understand the use of the Intel MKL sparse solver routines are discussed in the [Appendix A "Linear Solvers Basics"](#). If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes the direct sparse solver [PARDISO*](#) and the alternative interface for the direct sparse solver referred to here as [DSS interface](#); [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI); and [two preconditioners](#) based on the incomplete LU factorization technique.

PARDISO* - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the PARDISO* solver. The interface is Fortran, but it can be called from C programs by observing Fortran parameter passing and naming conventions used by the supported compilers and operating systems. A discussion of the algorithms used in the PARDISO* software and more information on the solver can be found at <http://www.pardiso-project.org>.

The current implementation of the PARDISO solver additionally supports the out-of-core (OOC) version.

The PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse symmetric and unsymmetric linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [[Schenk00-2](#)]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [[Schenk00](#), [Schenk01](#), [Schenk02](#), [Schenk03](#)]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

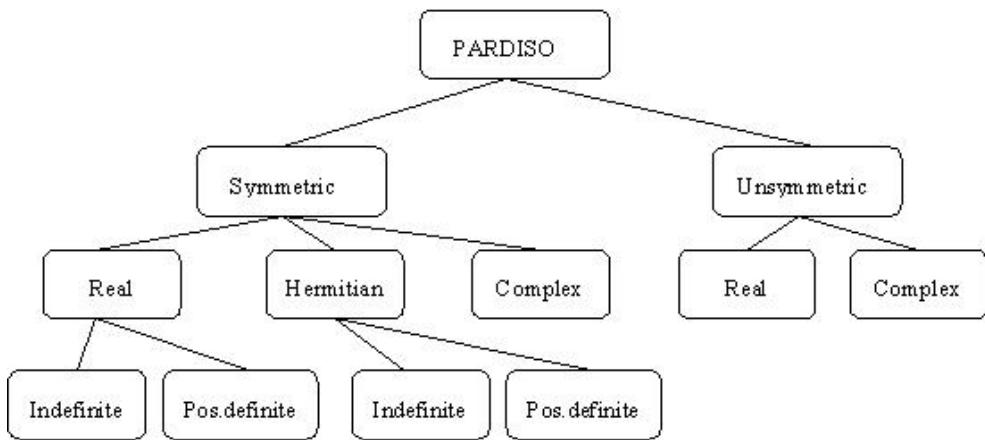

The following table lists the names of the PARDISO routines and describes their general use.

[PARDISO Routines](#)

Routine	Description
pardiso	Calculates the solution of a set of sparse linear equations with multiple right-hand sides.
pardisoinit	Initialize PARDISO with default parameters depending on the matrix type.
pardiso_64	Calculates the solution of a set of sparse linear equations with multiple right-hand sides, 64-bit integer version.
pardiso_getenv pardiso_setenv	Retrieves additional values from the PARDISO handle.
pardiso_getenv pardiso_setenv	Sets additional values in the PARDISO handle.

The PARDISO solver supports a wide range of sparse matrix types (see [the figure](#) below) and computes the solution of real or complex sparse linear system of equations on shared-memory multiprocessing architectures.

[Sparse Matrices That Can Be Solved with the PARDISO* Solver](#)

The PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

You can find a code example that uses the PARDISO interface routine to solve systems of linear equations in the `examples\solver\source` folder of your Intel MKL directory.

pardiso

Calculates the solution of a set of sparse linear equations with multiple right-hand sides.

Syntax

Fortran:

```
call pardiso (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm, msglvl,
b, x, error)
```

C:

```
pardiso (pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs, iparm,
&msglvl, b, x, &error);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl.h`

Description

The routine `pardiso` calculates the solution of a set of sparse linear equations

$A \cdot X = B$

with multiple right-hand sides, using a parallel LU , LDL or LL^T factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ matrices.

Supported Matrix Types.

The analysis steps performed by `pardiso` depends on the structure of the input matrix A .

Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1×1 and 2×2 Bunch and Kaufman pivoting for symmetric indefinite matrices, and an approximation of X is found by forward and backward substitution and iterative refinements.

Whenever numerically acceptable 1×1 and 2×2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinements may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinements is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of X is found by forward and backward substitution and iterative refinements.

Unsymmetric Matrices: The solver first computes a non-symmetric permutation P_{MPS} and scaling matrices D_r and D_c with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)_T$ followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_rAD_cP$$

with supernode pivoting matrices Q and R . When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of $\text{alpha} = \text{eps} * ||A2||_{\text{inf}}$, where eps is the machine precision, $A2 = P * P_{MPS} * D_r * A * D_c * P$, and $||A2||_{\text{inf}}$ is the infinity norm of the scaled and permuted matrix A . Any tiny pivots encountered during elimination are set to the sign $(1_{II}) * \text{eps} * ||A2||_{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Direct-Iterative Preconditioning for Unsymmetric Linear Systems.

The solver enables to use a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most of applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but the same identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. PARDISO uses a numerical factorization $A = LU$ for the first system and applies the factors L and U for the next steps in a preconditioned Krylow-Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to unsymmetric matrices in PARDISO. You can select the method using only one input parameter. For further details see the parameter description ($iparm(4)$, $iparm(20)$).

Single and Double Precision Computations.

PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, and input matrices can have large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made more roughly, only numerically stable process can use single precision.

Separate Forward and Backward Substitution.

The solver execution step (see [parameter phase = 33](#) below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal . This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix A ($mtype = 2$) is factored by PARDISO as $A = L \cdot L^T$. In this case the solution of the system $A \cdot x = b$ can be found as sequence of substitutions: $L \cdot y = b$ (forward substitution, $phase = 331$) and $L^T \cdot x = y$ (backward substitution, $phase = 333$).

A real unsymmetric matrix A ($mtype = 11$) is factored by PARDISO as $A = L \cdot U$. In this case the solution of the system $A \cdot x = b$ can be found by the following sequence: $L \cdot y = b$ (forward substitution, $phase = 331$) and $U \cdot x = y$ (backward substitution, $phase = 333$).

Solving a system with a real symmetric indefinite matrix A ($mtype = -2$) is slightly different from the cases above. PARDISO factors this matrix as $A = LDL^T$, and the solution of the system $A \cdot x = b$ can be calculated as the following sequence of substitutions: $L \cdot y = b$ (forward substitution, $phase = 331$) s: $D \cdot v = y$ (diagonal substitution, $phase = 332$) and, finally $L^T \cdot x = v$ (backward substitution, $phase = 333$). Diagonal substitution makes sense only for indefinite matrices ($mtype = -2, -4, 6$). For matrices of other types a solution can be found as described in the first two examples.

NOTE The number of refinement steps ($iparm(8)$) must be set to zero if a solution is calculated with separate substitutions ($phase = 331, 332, 333$), otherwise PARDISO produces the wrong result.

NOTE Different pivoting ($iparm(21)$) produces different LDL^T factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch and Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step ($phase=33$) regardless of the pivoting used.

Sparse Data Storage.

Sparse data storage in PARDISO follows the scheme described in [Sparse Matrix Storage Format](#) with ja standing for *columns*, ia for *rowIndex*, and a for *values*. The algorithms in PARDISO require column indices ja to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or unsymmetric matrices the diagonal elements are not necessary: they may be present or not.

NOTE The presence of diagonal elements for symmetric matrices is not mandatory starting from the Intel MKL 10.3 beta release.

CAUTION It's recommended to set explicitly zero diagonal elements for symmetric matrices because in the opposite case PARDISO creates internal copies of arrays ia , ja and a full of diagonal elements that requires additional memory and computational time. However, in general, memory and time overheads are not significant comparing to the memory and the time needed to factor and solve the matrix.

Input Parameters

NOTE Parameters types in this section are specified in FORTRAN 77 notation. See [PARDISO Parameters in Tabular Form](#) for detailed description of types of PARDISO parameters in C/Fortran 90 notations.

pt

INTEGER

Array, DIMENSION (64)

Pointer to the address of solver internal data. These addresses are passed to the solver and all related internal memory management is organized through this pointer.

NOTE *pt* is an integer array with 64 entries. It is very important that the pointer is initialized with zero at the first call of `pardiso`. After that first do not modify the pointer, as a serious memory leak can occur. The integer length must be 4 bytes on 32-bit operating systems and 8 bytes on 64-bit operating systems.

maxfct

INTEGER

Maximum number of factors with identical nonzero sparsity structure that must be keep at the same time in memory. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data management of the solver.

`pardiso` can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

mnum

INTEGER

Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be: $1 \leq mnum \leq maxfct$. In most applications this value is 1.

mtype

INTEGER

Defines the matrix type, which influences the pivoting method. The PARDISO solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and unsymmetric
13	complex and unsymmetric

phase

INTEGER

Controls the execution of the solver. Usually it is a two- or three-digit integer ij ($10i + j$, $1 \leq i \leq 3$, $i \leq j \leq 3$ for normal execution modes). The i digit indicates the starting phase of execution, j indicates the ending phase. PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including iterative refinements

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see [above](#)).

- Termination and Memory Release Phase ($phase \leq 0$)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The $phase$ parameter can have the following values:

<i>phase</i>	Solver Execution Steps
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
331	like $phase=33$, but only forward substitution
332	like $phase=33$, but only diagonal substitution
333	like $phase=33$, but only backward substitution
0	Release internal memory for L and U matrix number <i>mnum</i>
-1	Release all internal memory for all matrices

n

INTEGER

Number of equations in the sparse linear systems of equations $A^*X = B$.
Constraint: $n > 0$.

a

DOUBLE PRECISION - for real types of matrices ($mtype=1, 2, -2$ and 11)
and for double precision PARDISO ($iparm(28)=0$)

REAL - for real types of matrices ($mtype=1, 2, -2$ and 11) and for single precision PARDISO ($iparm(28)=1$)

DOUBLE COMPLEX - for complex types of matrices ($mtype=3, 6, 13, 14$ and -4) and for double precision PARDISO ($iparm(28)=0$)

COMPLEX - for complex types of matrices ($mtype=3, 6, 13, 14$ and -4) and for single precision PARDISO ($iparm(28)=1$)

Array. Contains the non-zero elements of the coefficient matrix A corresponding to the indices in ja . The size of a is the same as that of ja and the coefficient matrix can be either real or complex. The matrix must be stored in compressed sparse row format with increasing values of ja for each row. Refer to *values* array description in [Storage Formats for the Direct Sparse Solvers](#) for more details.

NOTE The non-zero elements of each row of the matrix A must be stored in increasing order. For symmetric or structural symmetric matrices, it is also important that the diagonal elements are available and stored in the matrix. If the matrix is symmetric, the array a is only accessed in the factorization phase, in the triangular solution and iterative refinement phase. Unsymmetric matrices are accessed in all phases of the solution process.

ia

INTEGER

Array, dimension $(n+1)$. For $i \leq n$, $ia(i)$ points to the first column index of row i in the array ja in compressed sparse row format. That is, $ia(I)$ gives the index of the element in array a that contains the first non-zero element from row i of A . The last element $ia(n+1)$ is taken to be equal to the number of non-zero elements in A , plus one. Refer to *rowIndex* array description in [Storage Formats for the Direct Sparse Solvers](#) for more details. The array ia is also accessed in all phases of the solution process. Indexing of ia is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter $iparm(35)$.

ja

INTEGER

Array $ja(*)$ contains column indices of the sparse matrix A stored in compressed sparse row format. The indices in each row must be sorted in increasing order. The array ja is also accessed in all phases of the solution process. For structurally symmetric matrices it is assumed that diagonal elements, which are zero, are also stored in the list of non-zero elements in a and ja . For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Storage Formats for the Direct Sparse Solvers](#).

Indexing of ja is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter $iparm(35)$.

perm

INTEGER

Array, dimension (n) . Holds the permutation vector of size n . You can use it to apply your own fill-in reducing ordering to the solver. The array $perm$ is defined as follows. Let A be the original matrix and $B = P^*A^*P^T$ be the permuted matrix. Row (column) i of A is the $perm(i)$ row (column) of B . The permutation vector $perm$ is used by the solver if $iparm(5) = 1$. The array $perm$ is also used to return the permutation vector calculated during fill-in reducing ordering stage. The permutation vector is returned into the $perm$ array if $iparm(5) = 2$. Indexing of $perm$ is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter $iparm(35)$.

NOTE The first elements of row, column and permutation are numbered as array elements 1 by default (Fortran style, or one based array indexing), but these first elements can be numbered as array elements 0 (C style, or zero based array indexing) by setting the appropriate value to the parameter $iparm(35)$.

nrhs

INTEGER

Number of right-hand sides that need to be solved for.

iparm

INTEGER

Array, dimension (64). This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver. If $iparm(1) = 0$, PARDISO uses default values for $iparm(2)$ through $iparm(64)$.

The individual components of the $iparm$ array are described below (some of them are described in the [Output Parameters](#) section).

iparm(1) - use default values.

If $iparm(1) = 0$, $iparm(2)$ through $iparm(64)$ are filled with default values, otherwise you must set all values in $iparm$ from $iparm(2)$ to $iparm(64)$.

iparm(2) - fill-in reducing ordering.

$iparm(2)$ controls the fill-in reducing ordering for the input matrix.

If $iparm(2) = 0$, the minimum degree algorithm is applied [Li99].

If $iparm(2) = 2$, the solver uses the nested dissection algorithm from the METIS package [Karypis98].

If $iparm(2) = 3$, the parallel (OpenMP) version of the nested dissection algorithm is used. It can decrease the time of computations on multi-core computers, especially when PARDISO Phase 1 takes significant time.

The default value of $iparm(2)$ is 2.

CAUTION You can control the parallel execution of the solver by explicitly setting the environment variable `MKL_NUM_THREADS`. If fewer processors are available than specified, the execution may slow down instead of speeding up. If the variable `MKL_NUM_THREADS` is not defined, then the solver uses all available processors.

iparm(3) - currently is not used.

iparm(4) - preconditioned CGS.

This parameter controls preconditioned CGS [Sonn89] for unsymmetric or structurally symmetric matrices and Conjugate-Gradients for symmetric matrices. $iparm(4)$ has the form $iparm(4) = 10 * L + K$.

The K and L values have the meanings as follows.

Value of κ	Description
0	The factorization is always computed as required by <i>phase</i> .
1	CGS iteration replaces the computation of LU . The preconditioner is LU that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.
2	CGS iteration for symmetric matrices replaces the computation of LU . The preconditioner is LU that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.

Value L :

The value L controls the stopping criterion of the Krylow-Subspace iteration:

$\text{eps}_{\text{CGS}} = 10^{-L}$ is used in the stopping criterion

$\|dx_i\| / \|dx_0\| < \text{eps}_{\text{CGS}}$

with $\|dx_i\| = \|\text{inv}(L^*U)^*r_i\|$ and r_i is the residue at iteration i of the preconditioned Krylow-Subspace iteration.

Strategy: A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If $\text{phase} = 23$, then the factorization for a given A is automatically recomputed in cases where the Krylow-Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylow-Subspace iteration is returned. Using $\text{phase} = 33$ results in an error message ($\text{error} = -4$) if the stopping criteria for the Krylow-Subspace iteration can not be reached. More information on the failure can be obtained from $\text{iparm}(20)$.

The default is $\text{iparm}(4) = 0$, and other values are only recommended for an advanced user. $\text{iparm}(4)$ must be greater or equal to zero.

Examples:

<i>iparm(4)</i>	Description
31	<i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for unsymmetric matrices
61	<i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for unsymmetric matrices
62	<i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric matrices

iparm(5) - user permutation.

This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another possible use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of PARDISO.

This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P^*A^*P^T$), or for using the permutation vector more than once for equal or similar matrices. For definition of the permutation, see the description of the *perm* parameter.

If $\text{parm}(5) = 0$ (default value), then the array *perm* is not used by PARDISO; if $\text{parm}(5) = 1$, then the user supplied fill-in reducing permutation in the array *perm* is used; if $\text{parm}(5) = 2$, then PARDISO returns the permutation vector into the array *perm*.

iparm(6) - write solution on x.

If $\text{iparm}(6) = 0$ (default value), then the array *x* contains the solution and the value of *b* is not changed.

If $\text{iparm}(6) = 1$, then the solver stores the solution in the right-hand side *b*.

Note that the array *x* is always used. The default value of *iparm(6)* is 0.

iparm(8) - iterative refinement step.

On entry to the solve and iterative refinement step, *iparm(8)* must be set to the maximum number of iterative refinement steps that the solver performs. The solver does not perform more than the absolute value of

iparm(8) steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved.

If *iparm(8) < 0*, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of *iparm(8)=0*) and the number of executed iterations is reported in *iparm(7)*.

The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and *iparm(8) = 0*.

The number of performed iterative refinement steps is reported in *iparm(7)*.

The default value for *iparm(8)* is 0.

iparm(9)

This parameter is reserved for future use. Its value must be set to 0.

iparm(10) - pivoting perturbation.

This parameter instructs PARDISO how to handle small pivots or zero pivots for unsymmetric matrices (*mtype =11* or *mtype =13*) and symmetric matrices (*mtype =-2*, *mtype =-4*, or *mtype =6*). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].

The magnitude of the potential pivot is tested against a constant threshold of

*alpha = eps * ||A2||_{inf},*

where *eps = 10^{(-iparm(10))}*, *A2 = P * P_{MPS} * D_r * A * D_c * P*, and *||A2||_{inf}* is the infinity norm of the scaled and permuted matrix *A*. Any tiny pivots encountered during elimination are set to the sign (*l_{III}*) * *eps * ||A2||_{inf}* - this trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with *eps = 10^{(-iparm(10))}*.

For unsymmetric matrices (*mtype =11* or *mtype =13*) the default value of *iparm(10)* is 13 and therefore *eps = 1.0E-13*.

For symmetric indefinite matrices (*mtype =-2*, *mtype =-4*, or *mtype =6*) the default value of *iparm(10)* is 8, and therefore *eps = 1.0E-8*.

iparm(11) - scaling vectors.

PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied only to unsymmetric matrices (*mtype =11* or *mtype =13*). The scaling can also be used for symmetric indefinite matrices (*mtype =-2*, *mtype =-4*, or *mtype =6*) when the symmetric weighted matchings are applied (*iparm(13)= 1*).

Use *iparm(11) = 1* (scaling) and *iparm(13) = 1* (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase=11*) you must provide the numerical values of the matrix *A* in case of scaling and symmetric weighted matching.

The default value of $iparm(11)$ is 1 for unsymmetric matrices ($mtype = 11$ or $mtype = 13$). The default value of $iparm(11)$ is 0 for symmetric indefinite matrices ($mtype = -2$, $mtype = -4$, or $mtype = 6$).

iparm(12) - solving with transposed or conjugate transposed matrix.

If $iparm(12) = 0$, PARDISO solves a linear system $Ax = b$ (default value).

If $iparm(12) = 1$, PARDISO solves a conjugate transposed system $A^Hx = b$ based on the factorization of the matrix A .

If $iparm(12) = 2$, PARDISO solves a transposed system $A^Tx = b$ based on the factorization of the matrix A .

 **NOTE** For real matrices the terms *conjugate transposed* and *transposed* are equivalent.

iparm(13) - improved accuracy using (non-)symmetric weighted matchings.

PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to our factorization methods and can be seen as a complement to the alternative idea of using more complete pivoting techniques during the numerical factorization.

Use $iparm(11)=1$ (scalings) and $iparm(13)=1$ (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase ($phase = 11$) you must provide the numerical values of the matrix A in the case of scalings and symmetric weighted matchings.

The default value of $iparm(13)$ is 1 for unsymmetric matrices ($mtype = 11$ or $mtype = 13$). The default value of $iparm(13)$ is 0 for symmetric matrices ($mtype = -2$, $mtype = -4$, or $mtype = 6$).

iparm(18) - numbers of non-zero elements in the factors.

If $iparm(18) < 0$ on entry, the solver reports the numbers of non-zero elements in the factors.

The default value of $iparm(18)$ is -1.

iparm(19) - MFLOPS of factorization.

If $iparm(19) < 0$ on entry, the solver reports the number of MFLOPS (1.0E6) that are necessary to factor the matrix A . Reporting this number increases the reordering time.

The default value of $iparm(19)$ is 0.

iparm(21) - pivoting for symmetric indefinite matrices.

$iparm(21)$ controls the pivoting method for sparse symmetric indefinite matrices.

If $iparm(21) = 0$, then 1x1 diagonal pivoting is used.

If $iparm(21) = 1$, then 1x1 and 2x2 Bunch and Kaufman pivoting is used in the factorization process.

NOTE Use $iparm(11) = 1$ (scaling) and $iparm(13) = 1$ (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.

The default value of $iparm(21)$ is 1. Bunch and Kaufman pivoting is available for matrices: $mtype=-2$, $mtype=-4$, or $mtype=6$.

$iparm(24)$ - parallel factorization control.

This parameter selects the scheduling method for the parallel numerical factorization.

If $iparm(24) = 0$ (default value), then PARDISO uses the previous parallel factorization.

If $iparm(24) = 1$, then PARDISO uses new two-level scheduling algorithm. This algorithm generally improves scalability in case of parallel factorization on many threads (more than eight).

The two-level scheduling factorization algorithm is enabled by default in previous MKL releases for matrices $mtype=11$. If you see performance degradation for such matrices with the default value, set manually $iparm(24)=1$.

$iparm(25)$ - parallel forward/backward solve control.

If $iparm(25) = 0$ (default value), then PARDISO uses a parallel algorithm for the solve step.

If $iparm(25) = 1$, then PARDISO uses sequential forward and backward solve.

This feature is available only for *in-core* version.

$iparm(27)$ - matrix checker.

If $iparm(27)=0$ (default value), PARDISO does not check the sparse matrix representation.

If $iparm(27)=1$, then PARDISO checks integer arrays ia and ja . In particular, PARDISO checks whether column indices are sorted in increasing order within each row.

$iparm(28)$ - sets single or double precision of PARDISO.

If $iparm(28)=0$, then the input arrays (matrix a , vectors x and b) and all internal arrays must be presented in double precision.

If $iparm(28)=1$, then the input arrays must be presented in single precision. In this case all internal computations are performed in single precision.

Depending on the sign of $iparm(8)$, refinement steps can be calculated in quad or double precision for double precision accuracy, and in double or single precision for single precision accuracy.

Default value of $iparm(28)$ is 0 (double precision).

Important $iparm(28)$ value is stored in the PARDISO handle between PARDISO calls, so the precision mode can be changed only during the solver's phase 1.

iparm(31) - partial solution for sparse right-hand sides and sparse solution.

This parameter controls the solution method if the right hand side contains a few nonzero components. It can be also used if only few components of the solution vector are needed, or if you want to reduce computation cost at solver step. To use this option define the input permutation vector *perm* so that *perm(i)* = 1 means that the *i*-th component in the right-hand side is nonzero or the *i*-th component in the solution vector is computed.

If *iparm(31)* = 0 (default value), this option is disabled.

If *iparm(31)* = 1, the right hand side must be sparse, and the *i*-th component in the solution vector is computed if *perm(i)* = 1. You can set *perm(i)* = 1 only if the *i*-th component of the right hand side is nonzero. If *iparm(31)* = 2, the right hand side must be sparse, all components of the solution vector are computed. *perm(i)* = 1 means that the *i*-th component of the right hand side is nonzero.

In the last case the computation cost at solver step is reduced due to reduced forward solver step.

To use *iparm(31)* = 2, you must set the *i*-th component of the right hand side to zero explicitly if *perm(i)* is not equal to 1.

If *iparm(31)* = 3, the right hand side can be of any type and you must set *perm(i)* = 1 to compute the *i*-th component in the solution vector.

The permutation vector *perm* must be present in all phases of Intel MKL PARDISO software. At the reordering step, the software overwrites the input vector *perm* by a permutation vector used by the software at the factorization and solver step. If *m* is the number of components such that *perm(i)* = 1, then the last *m* components of the output vector *perm* are a set of the indices *i* satisfying the condition *perm(i)* = 1 on input.

NOTE Turning on this option often increases time used by PARDISO for factorization and reordering steps, but it enables time to be reduced for the solver step.

Important This feature is available only for the *in-core* version, so to use it you must set *iparm(60)* = 0. Set the parameters *iparm(8)* (iterative refinement steps), *iparm(4)* (preconditioned CGS), and *iparm(5)* (user permutation) to 0 as well.

iparm(32) - *iparm(34)* - these parameters are reserved for future use. Their values must be set to 0.

iparm(35) - C or Fortran style array indexing.

iparm(35) determines the indexing base for input matrices.

If *iparm(35)* = 0 (default value), then PARDISO uses Fortran style indexing: first value is referenced as array element 1.

Otherwise PARDISO uses C style indexing: the first value is referenced as array element 0.

iparm(35) - *iparm(59)* - these parameters are reserved for future use. Their values must be set to 0.

iparm(60) - version of PARDISO.

iparm(60) controls what version of PARDISO - out-of-core (OC) version or in-core (IC) version - is used. The OC PARDISO can solve very large problems by holding the matrix factors in files on the disk. Because of that the amount of main memory required by OC PARDISO is significantly reduced.

If *iparm*(60) = 0 (default value), then IC PARDISO is used.

If *iparm*(60) = 1 - then IC PARDISO is used if the total memory of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: `MKL_PARDISO_OOC_MAX_CORE_SIZE` (its default value is 2000 MB) and `MKL_PARDISO_OOC_MAX_SWAP_SIZE` (its default value is 0 MB); otherwise OOC PARDISO is used. In this case amount of RAM used by OOC PARDISO can not exceed the value of `MKL_PARDISO_OOC_MAX_CORE_SIZE`.

If *iparm*(60) = 2 - then OOC PARDISO is used.

If *iparm*(60) is equal to 1 or 2, and the total peak memory needed for storing the local arrays is more than `MKL_PARDISO_OOC_MAX_CORE_SIZE`, the program stops with error -9. In this case, increase `MKL_PARDISO_OOC_MAX_CORE_SIZE`.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variable

`MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`.

Path and name are as follows:

<`MKL_PARDISO_OOC_CFG_PATH`>/<`MKL_PARDISO_OOC_CFG_FILE_NAME`> for Linux* OS, and

<`MKL_PARDISO_OOC_CFG_PATH`>\<`MKL_PARDISO_OOC_CFG_FILE_NAME`> for Windows* OS.

By default, the name of the file is `pardiso_ooc.cfg` and it is placed to the current directory.

All temporary data files can be deleted or stored when the calculations are completed in accordance with the value of the environmental variable `MKL_PARDISO_OOC_KEEP_FILE`. If it is set to 1 (default value), then all files are deleted, if it is set to 0, then all files are stored.

By default, the OOC PARDISO uses the current directory for storing data, and all work arrays associated with the matrix factors are stored in files named `ooc_temp` with different extensions. These default values can be changed by using the environmental variable `MKL_PARDISO_OOC_PATH`.

To set the environmental variables `MKL_PARDISO_OOC_MAX_CORE_SIZE`, `MKL_PARDISO_OOC_MAX_SWAP_SIZE`, `MKL_PARDISO_OOC_KEEP_FILE`, and `MKL_PARDISO_OOC_PATH`, create the configuration file with the following lines:

```
MKL_PARDISO_OOC_PATH = <path>\ooc_file
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where `<path>` is the directory for storing data, `ooc_file` is the file name without any extension, `N` is the maximum size of RAM in megabytes available for PARDISO (default value is 2000 MB), `K` is the maximum swap size in megabytes available for PARDISO (default value is 0 MB). Do not set `N` greater than the size of the RAM and `K` greater than the size of the swap.

WARNING The maximum length of the path lines in the configuration files is 1000 characters.

Alternatively the environment variables can be set via command line.

For Linux* OS:

```
export MKL_PARDISO_OOC_PATH = <path>/ooc_file
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_CORE_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows* OS:

```
set MKL_PARDISO_OOC_PATH = <path>\ooc_file
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_CORE_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

 **NOTE** The values specified in a command line have higher priorities - it means that if a variable is changed in the configuration file and in the command line, OOC PARDISO uses only value defined in the command line.

 **NOTE** You can switch between IC and OOC modes after the reordering phase. There are some recommendations and limitations:

- Set *iparm(60)* before reordering phase to get better PARDISO performance.
- Two-level factorization algorithm is not supported in the OOC mode. If you set two-level algorithm in the OOC mode then PARDISO returns error -1.
- Switching between IC and OOC modes after reordering phase is not available in sequential mode. The program returns error -1.

iparm(61), iparm(62), iparm(64) - these parameters are reserved for future use. Their values must be set to 0.

msglvl

INTEGER

Message level information. If *msglvl* = 0 then PARDISO generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

b

DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision PARDISO (*iparm(28)=0*)

REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision PARDISO (*iparm(28)=1*)

DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision PARDISO (*iparm(28)=0*)

COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision PARDISO (*iparm(28)=1*)

Array, dimension (*n, nrhs*). On entry, contains the right-hand side vector/matrix *B*, which is placed in memory contiguously. The *b(i+(k-1)×nrhs)* must hold the *i*-th component of *k*-th right-hand side vector. Note that *b* is only accessed in the solution phase.

Output Parameters

(See also [PARDISO Parameters in Tabular Form](#).)

pt

This parameter contains internal address pointers.

iparm

On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

iparm(7) - number of performed iterative refinement steps.

The number of iterative refinement steps that are actually performed during the solve step.

iparm(14) - number of perturbed pivots.

After factorization, *iparm*(14) contains the number of perturbed pivots during the elimination process for *mtype* =11, *mtype* =13, *mtype* =-2, *mtype* =-4, or *mtype* =-6.

iparm(15) - peak memory symbolic factorization.

The parameter *iparm*(15) reports the total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.

iparm(16) - permanent memory symbolic factorization.

The parameter *iparm*(16) reports the permanent memory in kilobytes from the analysis and symbolic factorization phase that the solver needs in the factorization and solve phases. This value is only computed in phase 1.

iparm(17) - size of factors /memory numerical factorization and solution.

The parameter *iparm*(17) provides the size in kilobytes of the total memory consumed by IC PARDISO for internal float point arrays. This parameter is computed in phase 1. See *iparm*(63) for the OOC mode. The total peak memory solver consumption for all phases is $\max(iparm(15), iparm(16)+iparm(17))$

iparm(18) - number of non-zero elements in factors.

The solver reports the numbers of non-zero elements on the factors if *iparm*(18) < 0 on entry.

iparm(19) - MFLOPS of factorization.

The solver reports the number of operations in MFLOPS (1.0E6 operations) that are necessary to factor the matrix *A* if *iparm*(19) < 0 on entry.

iparm(20) - CG/CGS diagnostics.

The value is used to give CG/CGS diagnostics (for example, the number of iterations and cause of failure):

If *iparm*(20)> 0, CGS succeeded, and the number of iterations executed are reported in *iparm*(20).

If *iparm*(20)< 0, iterations executed, but CG/CGS failed. The error report details in *iparm*(20) are of the form: *iparm*(20)= - it_cgs*10 - cgs_error.

If *phase*= 23, then the factors *L* and *U* are recomputed for the matrix *A* and the error flag *error*=0 in case of a successful factorization. If *phase* = 33, then *error* = -4 signals failure.

Description of *cgs_error* is given in the table below:

cgs_error	Description
1	fluctuations of the residue are too large

cgs_error	Description
2	$\ \mathbf{dx}_{\max_it_cgs/2} \ $ is too large (slow convergence)
3	stopping criterion is not reached at \max_it_cgs
4	perturbed pivots causes iterative refinement
5	factorization is too fast for this matrix. It is better to use the factorization method with $iparm(4)=0$

iparm(22) - inertia: number of positive eigenvalues.

The parameter $iparm(22)$ reports the number of positive eigenvalues for symmetric indefinite matrices.

iparm(23) - inertia: number of negative eigenvalues.

The parameter $iparm(23)$ reports the number of negative eigenvalues for symmetric indefinite matrices.

iparm(30) - the number of the equation where PARDISO detects zero or negative pivot

If the solver detects a zero or negative pivot for matrix types $mtype = 2$ (real positive definite matrix) and $mtype = 4$ (complex and Hermitian positive definite matrices), the factorization is stopped, PARDISO returns immediately with an error ($error = -4$) and $iparm(30)$ contains the number of the equation where the first zero or negative pivot is detected.

iparm(63) - size of the minimum OOC memory for numerical factorization and solution.

The parameter $iparm(63)$ provides the size in kilobytes of the minimum memory required by OOC PARDISO for internal float point arrays. This parameter is computed in phase 1.

Total peak memory consumption of OOC PARDISO can be estimated as $\max(iparm(15), iparm(16)+iparm(63))$

b On output, the array is replaced with the solution if $iparm(6) = 1$.

x DOUBLE PRECISION - for real types of matrices ($mtype=1, 2, -2$ and 11) and for double precision PARDISO ($iparm(28)=0$)

REAL - for real types of matrices ($mtype=1, 2, -2$ and 11) and for single precision PARDISO ($iparm(28)=1$)

DOUBLE COMPLEX - for complex types of matrices ($mtype=3, 6, 13, 14$ and -4) and for double precision PARDISO ($iparm(28)=0$)

COMPLEX - for complex types of matrices ($mtype=3, 6, 13, 14$ and -4) and for single precision PARDISO ($iparm(28)=1$)

Array, dimension ($n, nrhs$). If $iparm(6)=0$ it contains solution vector/
matrix *x*, which is placed contiguously in memory. The $x(i+(k-1) \times nrhs)$ element must hold the *i*-th component of the *k*-th solution vector. Note that *x* is only accessed in the solution phase.

error

INTEGER

The error indicator according to the below table:

error	Information
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem

error	Information
-4	zero pivot, numerical factorization or iterative refinement problem
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	problems with opening OOC temporary files
-11	read/write problems with the OOC data file

[mkl_progress](#)

pardisoinit

Initialize PARDISO with default parameters in accordance with the matrix type.

Syntax

Fortran:

```
call pardisoinit (pt, mtype, iparm)
```

C:

```
pardisoinit (pt, &mtype, iparm);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_pardiso.f90
- C: mkl.h

Description

This function initializes PARDISO internal address pointer *pt* with zero values (as needed for the very first call of PARDISO) and sets default *iparm* values in accordance with the matrix type. Intel MKL supplies the pardisoinit routine to be compatible with PARDISO 3.2 or lower distributed by the University of Basel.

NOTE An alternative way to set default PARDISO *iparm* values is to call pardiso with *iparm*(1)=0. In this case you must initialize the internal address pointer *pt* with zero values manually.

NOTE The pardisoinit routine initializes only the in-core version of PARDISO. Switching on the out-of core version of PARDISO as well as changing default *iparm* values can be done after the call to pardisoinit but before the first call to pardiso.

Input Parameters

NOTE Parameters types in this section are specified in FORTRAN 77 notation. See [PARDISO Parameters in Tabular Form](#) section for detailed description of types of PARDISO parameters in C/Fortran 90 notations.

mtype

INTEGER

This scalar value defines the matrix type. Based on this value `pardisoinit` sets default values for the `iparm` array. Refer to the section [PARDISO Parameters in Tabular Form](#) for more details about the default values of PARDISO.

Output Parameters

pt

INTEGER for 32-bit architectures

INTEGER*8 for 64-bit architectures

Array, DIMENSION (64)

Solver internal data address pointer. These addresses are passed to the solver, and all related internal memory management is organized through this array. The `pardisoinit` routine nullifies the array *pt*.

NOTE It is very important that the pointer *pt* is initialized with zero before the first call of PARDISO. After that first call you should never modify the pointer, as a serious memory leak can occur.

iparm

INTEGER

Array, dimension (64). This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver. The `pardisoinit` routine fills-in the *iparm* array with the default values. Refer to the section [PARDISO Parameters in Tabular Form](#) for more details about the default values of PARDISO.

[pardiso_64](#)

Calculates the solution of a set of sparse linear equations with multiple right-hand sides, 64-bit integer version.

Syntax

Fortran:

```
call pardiso_64 (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm,
msglvl, b, x, error)
```

C:

```
pardiso_64 (pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs, iparm,
&msglvl, b, x, &error);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl.h`

Description

`pardiso_64` is an alternative ILP64 (64-bit integer) version of the `pardiso` routine (see [Description](#) section for more details). The interface of `pardiso_64` is equal to the interface of `pardiso`, but it accepts and returns all INTEGER data as `INTEGER*8`.

Use `pardiso_64` interface for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel MKL functionality. In other words, if you use 64-bit integer version (`pardiso_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `pardiso_64` may perform slower than regular `pardiso` on reordering and symbolic factorization phase.

NOTE `pardiso_64` is supported only in the 64-bit libraries. If `pardiso_64` is called from the 32-bit libraries, it returns `error = -12`.

Input Parameters

The input parameters of `pardiso_64` are equal to the [input parameters of `pardiso`](#), but `pardiso_64` accepts all INTEGER data as `INTEGER*8`.

Output Parameters

The output parameters of `pardiso_64` are equal to [output parameters of `pardiso`](#), but `pardiso_64` returns all INTEGER data as `INTEGER*8`.

[mkl_progress](#)

`pardiso_getenv`, `pardiso_setenv`

Retrieves additional values from the PARDISO handle or sets them in it.

Syntax

```
error = pardiso_getenv(handle, param, value)
error = pardiso_setenv(handle, param, value)
```

`outputtext`(Interface):

```
_INTEGER_t pardiso_getenv (const _MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM* param, char* value);
_INTEGER_t pardiso_setenv (_MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM* param, const char* value);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl.h`

NOTE `pardiso_setenv` requires the `value` parameter to be converted to the string in C notation if it is called from Fortran. You can do this using `mkl_cvt_to_null_terminated_str` subroutine declared in the `mkl_dss.f77` or `mkl_dss.f90` include files (see the example below).

Description

These functions operate with the PARDISO handle. The `pardiso_getenv` routine retrieves additional values from the PARDISO handle, and `pardiso_setenv` sets specified values in the PARDISO handle.

These functions enable retrieving and setting the name of the PARDISO OOC file.

To retrieve the PARDISO OOC file name, you can apply this function to any non-empty handle.

To set the the PARDISO OOC file name in the handle you must apply the function before reordering stage. That is you must apply the function only for the empty handle. This is because OOC file name is stored in the handle after reordering stage and it is not changed during further computations.

NOTE 1024-byte internal buffer is used inside PARDISO for storing OOC file name. Allocate 1024-byte buffer (`value` parameter) for passing it to `pardiso_getenv` function.

Input Parameters

<code>handle</code>	Input parameter for <code>pardiso_getenv</code> . Data object of the <code>MKL_DSS_HANDLE</code> type (see DSS Interface Description).
<code>param</code>	<code>INTEGER</code> . Specifies the required parameter. The only value is <code>PARDISO_OCC_FILE_NAME</code> , defined in the corresponding include file.
<code>value</code>	Input parameter for <code>pardiso_setenv</code> . <code>STRING</code> . Contains the name of the OOC file that must be used in the handle.

Output Parameters

<code>value</code>	Output parameter for <code>pardiso_getenv</code> . <code>STRING</code> . Contains the name of the OOC file that is used in the handle.
<code>handle</code>	Output parameter for <code>pardiso_setenv</code> . Data object of the <code>MKL_DSS_HANDLE</code> type (see DSS Interface Description).

Example (FORTRAN 90)

```

INCLUDE 'mkl_pardiso.f90'
INCLUDE 'mkl_dss.f90'
PROGRAM pardiso_sym_f90
USE mkl_pardiso
USE mkl_dss

INTEGER*8 pt(64)
CHARACTER*1024 file_name
INTEGER buff(256), bufLen, error

pt(1:64) = 0

file_name = 'pardiso_ooc_file'
bufLen = len(trim(file_name))
call mkl_cvt_to_null_terminated_str(buff, bufLen, trim(file_name))
error = pardiso_setenv(pt, PARDISO_OOC_FILE_NAME, buff)

! call pardiso() here

END PROGRAM

```

PARDISO Parameters in Tabular Form

The following table lists all parameters of PARDISO and gives their brief descriptions.

Parameter	Type	Description	Values	Comments	In/ Out
<i>pt(64)</i>	FORTRAN 77: INTEGER on 32-bit architectures, INTEGER*8 on 64- bit architectures Fortran 90: TYPE (MKL_PARDIS O_HANDLE), INTENT (INOUT) C: void*	Solver internal data address pointer	0	Must be initialized by zeros and never be modified later	in/ out
<i>maxfct</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: _INTEGER_t*	Maximal number of factors in memory	>0	Generally used value is 1	in
<i>mnum</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: _INTEGER_t*	The number of matrix (from 1 to <i>maxfct</i>) to solve	[1; <i>maxfct</i>]	Generally used value is 1	in
<i>mtype</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: _INTEGER_t*	Matrix type	1 2 -2 3 4 -4 6 11 13	Real and structurally symmetric Real and symmetric positive definite Real and symmetric indefinite Complex and structurally symmetric Complex and Hermitian positive definite Complex and Hermitian indefinite Complex and symmetric matrix Real and unsymmetric matrix Complex and unsymmetric matrix	in
<i>phase</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Controls the execution of the solver	11 12	Analysis Analysis, numerical factorization	in

Parameter	Type	Description	Values	Comments	In/ Out

<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Number of equations in the sparse linear system $A^*X = B$	>0		in
<i>a</i> (*)	FORTRAN 77: PARDISO_DATA_TY PE ¹) Fortran 90: PARDISO_DATA_TY PE ¹), INTENT(IN) C: <code>void*</code>	Contains the non-zero elements of the coefficient matrix <i>A</i>	*	The size of <i>a</i> is the same as that of <i>ja</i> , and the coefficient matrix can be either real or complex. The matrix must be stored in CSR format with increasing values of <i>ja</i> for each row	in
<i>ia</i> (<i>n</i> +1)	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t*</code>	<i>rowIndex</i> array in CSR format	>=0	0 < <i>ia</i> (<i>i</i>) <= <i>ia</i> (<i>i</i> +1) <i>ia</i> (<i>i</i>) gives the index of the element in array <i>a</i> that contains the first non-zero element from row <i>i</i> of <i>A</i> . The last element <i>ia</i> (<i>n</i> +1) is taken to be equal to the number of non-zero elements in <i>A</i> , plus one. Note: <i>iparm</i> (35) indicates whether row/column indexing starts from 1 or 0.	in
<i>ja</i> (*)	FORTRAN 77: INTEGER	<i>columns</i> array in CSR format	>=0	The indices in each row must be sorted in increasing order. For	in

Parameter	Type	Description	Values	Comments	In/ Out
	Fortran 90: INTEGER, INTENT (IN) C: <code>_INTEGER_t*</code>			symmetric and structurally symmetric matrices zero diagonal elements are also stored in a and ja . For symmetric matrices, the solver needs only the upper triangular part of the system.	
				Note: $iparm(35)$ indicates whether row/column indexing starts from 1 or 0.	
$perm(n)$	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (INOUT) C: <code>_INTEGER_t*</code>	Holds the permutation vector of size n	$>=0$	Let $B = P^* A^* PT$ be the permuted matrix. Row (column) i of A is the $perm(i)$ row (column) of B . The numbering of the array must describe a permutation.	in/ out
				You can apply your own fill-in reducing ordering ($iparm(5)=1$) or return the permutation from the solver ($iparm(5)=2$).	
				Note: $iparm(35)$ indicates whether row/column indexing starts from 1 or 0.	
$nrhs$	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: <code>_INTEGER_t*</code>	Number of right-hand sides that need to be solved for	$>=0$	Generally used value is 1	in
$iparm(64)$	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (INOUT) C: <code>_INTEGER_t*</code>	This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver	*	If $iparm(1)=0$, PARDISO fills $iparm(2)$ through $iparm(64)$ with default values and uses them.	in/ out
$msglvl$	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: <code>_INTEGER_t*</code>	Message level information	0 1	PARDISO generates no output PARDISO prints statistical information	in

Parameter	Type	Description	Values	Comments	In/ Out
$b(n*nrhs)$	FORTRAN 77: PARDISO_DATA_TY PE^1) Fortran 90: PARDISO_DATA_TY PE^1 , INTENT (INOUT) C: void*	Right-hand side vectors	*	On entry, contains the right hand side vector/matrix B , which is placed contiguously in memory. The $b(i+(k-1) \times nrhs)$ element must hold the i -th component of k -th right-hand side vector. Note that b is only accessed in the solution phase.	in/ out
$x(n*nrhs)$	FORTRAN 77: PARDISO_DATA_TY PE^1) Fortran 90: PARDISO_DATA_TY PE^1 , INTENT (OUT) C: void*	Solution vectors	*	On output, the array is replaced with the solution if $\text{iparm}(6)=1$.	out
error	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (OUT) C: _INTEGER_t*	Error indicator	0 -1 -2 -3 -4 -5 -6 -7 -8 -9 -10 -11	No error Input inconsistent Not enough memory Reordering problem Zero pivot, numerical factorization or iterative refinement problem Unclassified (internal) error Reordering failed (matrix types 11 and 13 only) Diagonal matrix is singular 32-bit integer overflow problem Not enough memory for OOC Problems with opening OOC temporary files Read/write problems with the OOC data file	out

¹⁾ See description of PARDISO_DATA_TYPE in the table below.

The following table lists the values of `PARDISO_DATA_TYPE` depending on the matrix types and values of the parameter `iparm(28)`.

Data type value	Matrix type <code>mtype</code>	<code>iparm(28)</code>	comments
DOUBLE PRECISION	1, 2, -2, 11	0	Real matrices, double precision
REAL		1	Real matrices, single precision
DOUBLE COMPLEX	3, 6, 13, 4, -4	0	Complex matrices, double precision
COMPLEX		1	Complex matrices, single precision

The following table lists all individual components of the PARDISO `iparm()` parameter and their brief descriptions. Components not listed in the table must be initialized with 0. Default values in the column **Values** are denoted as `*X`.

Component	Description	Values	Comments	In/Out
INPUT, INPUT/OUTPUT PARAMETERS				
<code>iparm(1)</code>	Use default values	0 !=0	<code>iparm(2) - iparm(64)</code> are filled with default values. You must supply all values in components <code>iparm(2) - iparm(64)</code>	in
<code>iparm(2)</code>	Fill-in reducing ordering for the input matrix	0 2* 3	The minimum degree algorithm. The nested dissection algorithm from the METIS package The parallel (OpenMP) version of the nested dissection algorithm.	in
<code>iparm(4)</code>	Preconditioned CGS/CG	0* 10^L+1 10^L+2	Do not perform preconditioned Krylow-Subspace iterations. CGS iteration replaces the computation of LU. The preconditioner is LU that is computed at the previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns. L controls the stopping criterion of the Krylow-Subspace iteration: $\text{epsCGS} = 10^{-L}$ is used in the stopping criterion $\ dx_i\ / \ dx_0\ < \text{epsCGS}$, with $\ dx_i\ = \ \text{inv}(L^*U)^*ri\ $ and ri is the residuum at iteration i of the preconditioned Krylow-Subspace iteration.	in
<code>iparm(5)</code>	User permutation	0* 1 2	User permutation in <code>perm</code> array is ignored. PARDISO uses the user supplied fill-in reducing permutation from <code>perm</code> array. <code>iparm(2)</code> is ignored. PARDISO returns the permutation vector computed at phase 1 into <code>perm</code> array	in

Compo nent	Description	Values	Comments	In/ Out
<i>iparm</i> (6)	Write solution on <i>x</i>	0*	The array <i>x</i> contains the solution; right-hand side vector <i>b</i> is kept unchanged.	in
		1	The solver stores the solution on the right-hand side <i>b</i> . Note that the array <i>x</i> is always used.	
<i>iparm</i> (8)	Iterative refinement step	0*	The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization.	in
		>0	Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm</i> (8) steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. The number of executed iterations is reported in <i>iparm</i> (7).	
		<0	Same as above, but the accumulation of the residuum uses extended precision real and complex data types.	
<i>iparm</i> (10)	Pivoting perturbation	*	This parameter instructs PARDISO how to handle small pivots or zero pivots for unsymmetric matrices (<i>mtype</i> = 11, <i>mtype</i> = 13) and symmetric matrices (<i>mtype</i> = -2, <i>mtype</i> = -4, <i>mtype</i> = 6). Small pivots are perturbed with <i>eps</i> = $10^{(-iparm(10))}$.	in
		13*	The default value for unsymmetric matrices (<i>mtype</i> = 11, <i>mtype</i> = 13), <i>eps</i> = $10^{(-13)}$.	
		8*	The default value for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> = -4, <i>mtype</i> = 6), <i>eps</i> = $10^{(-8)}$.	
		0*	Disable scaling. Default for symmetric indefinite matrices.	
<i>iparm</i> (11)	Scaling	1*	Enable scaling. Default for unsymmetric matrices. Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to unsymmetric matrices (<i>mtype</i> = 11, <i>mtype</i> = 13). The scaling can also be used for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> = -4, <i>mtype</i> = 6) when the symmetric weighted matchings are applied (<i>iparm</i> (13) = 1). Note that in the analysis phase (<i>phase</i> =11) you must provide the numerical values of the matrix <i>A</i> in case of scaling.	in

Compo nent	Description	Values	Comments	In/ Out
<i>iparm</i> (12)	Solving with transposed or conjugate transposed matrix A	0*	Solve a $Ax=b$ linear system.	
		1	Solve a conjugate transposed system $A^H x = b$ based on the factorization of the matrix A .	
		2	Solve a transposed system $A^T x = b$ based on the factorization of the matrix A .	
<i>iparm</i> (13)	Improved accuracy using (non-) symmetric weighted matching	0*	Disable matching. Default for symmetric indefinite matrices.	in
		1*	Enable matching. Default for symmetric indefinite matrices.	
			Maximum weighted matching algorithm to permute large elements close to the diagonal.	
			It is recommended to use <i>iparm</i> (11) = 1 (scaling) and <i>iparm</i> (13) = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.	
			Note that in the analysis phase (<i>phase</i> =11) you must provide the numerical values of the matrix A in case of symmetric weighted matching.	
<i>iparm</i> (18)	Report the number of non-zero elements in the factors	<0	Enable reporting if <i>iparm</i> (18) < 0 on entry. The default value is -1.	in/ out
		≥ 0	Disable reporting.	
<i>iparm</i> (19)	Report Mflops that are necessary to factor the matrix A .	<0	Enable report if <i>iparm</i> (18) < 0 on entry. This increases the reordering time.	in/ out
		≥ 0	Disable report. 0 is a default value.	
<i>iparm</i> (21)	Pivoting for symmetric indefinite matrices	0	Apply 1x1 diagonal pivoting during the factorization process.	in
		1*	Apply 1x1 and 2x2 Bunch and Kaufman pivoting during the factorization process.	
<i>iparm</i> (24)	parallel factorization control	0	PARDISO uses the previous algorithm for factorization. Default value.	in
		1	PARDISO uses new two-level factorization algorithm.	
<i>iparm</i> (25)	Parallel forward/backward solve control	0	PARDISO uses the parallel algorithm for solve step. Default value.	in
		1	PARDISO uses the sequential forward and backward solve.	
<i>iparm</i> (27)	Matrix checker	0*	PARDISO does not check the sparse matrix representation.	in
		1	PARDISO checks integer arrays <i>ia</i> and <i>ja</i> . In particular, PARDISO checks whether column indices are sorted in increasing order within each row.	
<i>iparm</i> (28)	Single or double precision of PARDISO	0*	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.	in

Compo nent	Description	Values	Comments	In/ Out
<i>iparm</i> (31)	Enables solving partially for sparse right-hand sides and sparse solution	1	Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.	
		0	Disables this option. Default value.	in
		1	The right hand side is assumed to be sparse, <i>perm(i)=1</i> means that the <i>i</i> -th component of the right hand side is nonzero, and this component of the solution vector is computed.	
		2	The right hand side is assumed to be sparse, <i>perm(i)=1</i> means that the <i>i</i> -th component of the right hand side is nonzero, and all components of the solution vector are computed.	
<i>iparm</i> (35)	One- or zero-based indexing of columns and rows	3	The right hand side can be of any type. If <i>perm(i)=1</i> , the <i>i</i> -th component of the solution vector is computed.	
		0*	One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1. Default value.	in
		1	Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0.	
<i>iparm</i> (60)	PARDISO mode	0*	In-core PARDISO	in
		1	In-core PARDISO is used if the total memory needed for storing the matrix factors is less than the value of the environment variable <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> . Otherwise out-of-core (OOC) PARDISO is used.	
		2	Out-of-core (OOC) PARDISO The OOC PARDISO can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC PARDISO is significantly reduced.	
OUTPUT PARAMETERS				
<i>iparm</i> (7)	Number of performed iterative refinement steps	>=0	Reports the number of iterative refinement steps that were actually performed during the solve step.	out
<i>iparm</i> (14)	Number of perturbed pivots	>=0	After factorization, contains the number of perturbed pivots for the matrix types: 11, 13, -2, -4 and -6.	out
<i>iparm</i> (15)	Peak memory on symbolic factorization	>0 KB	The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.	out
<i>iparm</i> (16)	Permanent memory on symbolic factorization	>0 KB	Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases. This value is only computed in phase 1.	out

Component	Description	Values	Comments	In/ Out
<i>iparm</i> (17)	Size of factors/Peak memory on numerical factorization and solution	>0 KB	This parameter provides the size in kilobytes of the total memory consumed by in-core PARDISO for internal float point arrays. This parameter is computed in phase 1. See <i>iparm</i> (63) for the OOC mode. The total peak memory consumed by PARDISO is $\max(iparm(15), iparm(16)+iparm(17))$	out
<i>iparm</i> (20)	CG/CGS diagnostics	>0 <0	CGS succeeded, reports the number of completed iterations. CG/CGS failed (<i>error</i> =-4 after the solution phase) $iparm(20) = - it_cgs * 10 - cgs_error.$ Possible values of <i>cgs_error</i> : 1 - fluctuations of the residuum are too large 2 - $\ dx\ $ at $max_it_cgs/2$ is too large (slow convergence) 3 - stopping criterion is not reached at max_it_cgs 4 - perturbed pivots causes iterative refinement	out
<i>iparm</i> (22)	Inertia: number of positive eigenvalues	>=0	PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices	out
<i>iparm</i> (23)	Inertia: number of negative eigenvalues	>=0	PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.	out
<i>iparm</i> (30)	Number of zero or negative pivots	>=0	If PARDISO detects zero or negative pivot for <i>mtype</i> =2 or <i>mtype</i> =4 types, the factorization is stopped, PARDISO returns immediately with an <i>error</i> = -4, and <i>iparm</i> (30) reports the number of the equation where the first zero or negative pivot is detected.	out
<i>iparm</i> (63)	Size of the minimum OOC memory for numerical factorization and solution	>0 KB	This parameter provides the size in kilobytes of the minimum memory required by OOC PARDISO for internal float point arrays. This parameter is computed in phase 1. Total peak memory consumption of OOC PARDISO can be estimated as $\max(iparm(15), iparm(16)+iparm(63))$	out

Direct Sparse Solver (DSS) Interface Routines

Intel MKL supports the DSS interface, an alternative to the PARDISO* interface for the direct sparse solver. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and utilizes the general scheme described in [Appendix A Linear Solvers Basics](#) for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process and an auxiliary routine for passing character strings from Fortran routines to C routines.

The current implementation of the DSS interface additionally supports the out-of-core (OOC) mode.

[Table "DSS Interface Routines"](#) lists the names of the routines and describes their general use.

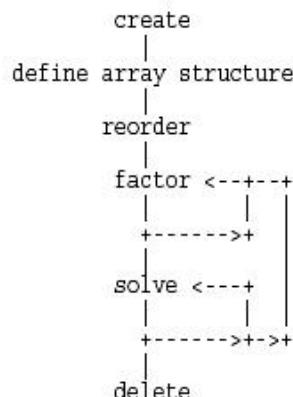

DSS Interface Routines

Routine	Description
dss_create	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.
dss_define_structure	Informs the solver of the locations of the non-zero elements of the array.
dss_reorder	Based on the non-zero structure of the matrix, computes a permutation vector to reduce fill-in during the factoring process.
dss_factor_real, dss_factor_complex	Computes the LU , LDL^T or LL^T factorization of a real or complex matrix.
dss_solve_real, dss_solve_complex	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
dss_delete	Deletes all data structures created during the solving process.
dss_statistics	Returns statistics about various phases of the solving process.
mkl_cvt_to_null_terminated_str	Passes character strings from Fortran routines to C routines.

To find a single solution vector for a single system of equations with a single right hand side, invoke the Intel MKL DSS interface routines in this order:

1. dss_create
2. dss_define_structure
3. dss_reorder
4. dss_factor_real, dss_factor_complex
5. dss_solve_real, dss_solve_complex
6. dss_delete

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is sometimes necessary to invoke the Intel MKL sparse routines in an order other than that listed, which is possible using the DSS interface. The solving process is conceptually divided into six phases. [Figure "Typical order for invoking DSS interface routines"](#) indicates the typical order in which the DSS interface routines can be invoked.

Typical order for invoking DSS interface routines

See the code examples that use the DSS interface routines to solve systems of linear equations in the examples\solver\source folder of your Intel MKL directory (dss_sym_f.f, dss_sym_c.c, dss_sym_f90.f90).

DSS Interface Description

Each DSS routine reads from or writes to a data object called a *handle*. Refer to [Memory Allocation and Handles](#) to determine the correct method for declaring a handle argument for each language. For simplicity, the descriptions in DSS routines refer to the data type as `MKL_DSS_HANDLE`.

C and C++ programmers should refer to [Calling Sparse Solver and Preconditioner Routines from C C++](#) for information on mapping Fortran types to C/C++ types.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see [Implementation Details](#)). The routines accept options for setting the message and termination levels as described in [Table "Symbolic Names for the Message and Termination Levels Options"](#). Additionally, each routine accepts the option `MKL_DSS_DEFAULTS` that sets the default values (as documented) for *opt* to the routine.

Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
<code>MKL_DSS_MSG_LVL_SUCCESS</code>	<code>MKL_DSS_TERM_LVL_SUCCESS</code>
<code>MKL_DSS_MSG_LVL_INFO</code>	<code>MKL_DSS_TERM_LVL_INFO</code>
<code>MKL_DSS_MSG_LVL_WARNING</code>	<code>MKL_DSS_TERM_LVL_WARNING</code>
<code>MKL_DSS_MSG_LVL_ERROR</code>	<code>MKL_DSS_TERM_LVL_ERROR</code>
<code>MKL_DSS_MSG_LVL_FATAL</code>	<code>MKL_DSS_TERM_LVL_FATAL</code>

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

You can specify both message and termination level for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
CALL dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL DSS routines do not make copies of the user input arrays.

WARNING Do not modify the contents of these arrays after they are passed to one of the solver routines.

DSS Routines

dss_create

Initializes the solver.

Syntax

C:

```
dss_create(handle, opt)
```

Fortran:

```
call dss_create(handle, opt)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

The `dss_create` routine initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel MKL DSS routines must use the value of the handle returned by `dss_create`.

WARNING Do not write the value of handle directly.

The default value of the parameter `opt` is

```
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.
```

By default, the DSS routines use double precision for solving systems of linear equations. The precision used by the DSS routines can be set to single mode by adding the following value to the `opt` parameter:

```
MKL_DSS_SINGLE_PRECISION.
```

As for PARDISO, input data and internal arrays are required to have single precision.

By default, the DSS routines use Fortran style indexing for input arrays of integer types (the first value is referenced as array element 1). The indexing can be set to C style (the first value is referenced as array element 0) by adding the following value to the `opt` parameter:

```
MKL_DSS_ZERO_BASED_INDEXING.
```

This parameter can also control number of refinement steps used on the solution stage by specifying the two following values:

```
MKL_DSS_REFINEMENT_OFF - maximum number of refinement steps is set to zero;
```

```
MKL_DSS_REFINEMENT_ON (default value) - maximum number of refinement steps is set to 2.
```

By default, DSS uses in-core computations. To launch the out-of-core version of DSS (OOC DSS) you can add to this parameter one of two possible values: `MKL_DSS_OOC_STRONG` and `MKL_DSS_OOC_VARIABLE`.

`MKL_DSS_OOC_STRONG` - OOC DSS is used.

`MKL_DSS_OOC_VARIABLE` - if the memory needed for the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE`, then the OOC DSS uses the in-core kernels of PARDISO, otherwise it uses the OOC computations.

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of RAM allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 MB. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the [pardiso](#) description above).

WARNING Do not change the OOC DSS settings after they are specified in the routine `dss_create`.

Input Parameters

Name	Type	Description
<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Parameter to pass the DSS options. The default value is <code>MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR</code> .

Output Parameters

Name	Type	Description
<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE(<code>(MKL_DSS_HANDLE)</code>), INTENT(OUT) C: <code>_MKL_DSS_HANDLE_t*</code>	Pointer to the data structure storing intermediate DSS results (<code>MKL_DSS_HANDLE</code>).

Return Values

`MKL_DSS_SUCCESS`
`MKL_DSS_INVALID_OPTION`
`MKL_DSS_OUT_OF_MEMORY`
`MKL_DSS_MSG_LVL_ERR`
`MKL_DSS_TERM_LVL_ERR`

`dss_define_structure`

Communicates locations of non-zero elements in the matrix to the solver.

Syntax

C:

```
dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

Fortran:

```
call dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_dss.f90`
- C: `mkl.h`

Description

The routine `dss_define_structure` communicates the locations of the `nNonZeros` number of non-zero elements in a matrix of `nRows * nCols` size to the solver.

The Intel MKL DSS software operates only on square matrices, so `nRows` must be equal to `nCols`.

To communicate the locations of non-zero elements in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying the value for the options argument *opt*. You can set the following values for real matrices:

- MKL_DSS_SYMMETRIC_STRUCTURE
- MKL_DSS_SYMMETRIC
- MKL_DSS_NON_SYMMETRIC

and for complex matrices:

- MKL_DSS_SYMMETRIC_STRUCTURE_COMPLEX
- MKL_DSS_SYMMETRIC_COMPLEX
- MKL_DSS_NON_SYMMETRIC_COMPLEX

The information about the matrix type must be defined in `dss_define_structure`.

2. Provide the actual locations of the non-zeros by means of the arrays `rowIndex` and `columns` (see [Sparse Matrix Storage Format](#)).

Input Parameters

Name	Type	Description
<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Parameter to pass the DSS options. The default value for the matrix structure is MKL_DSS_SYMMETRIC.
<i>rowIndex</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Array of size $\min(nRows, nCols) + 1$. Defines the location of non-zero entries in the matrix.
<i>nRows</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Number of rows in the matrix.
<i>nCols</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Number of columns in the matrix.
<i>columns</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Array of size <i>nNonZeros</i> . Defines the location of non-zero entries in the matrix.
<i>nNonZeros</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Number of non-zero elements in the matrix.

Output Parameters

Name	Type	Description
<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (<code>MKL_DSS_HANDLE</code>), INTENT(INOUT)	Pointer to the data structure storing intermediate DSS results (<code>MKL_DSS_HANDLE</code>).

Name	Type	Description
C:	_MKL_DSS_HANDLE_t*	

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_STRUCTURE_ERR
 MKL_DSS_ROW_ERR
 MKL_DSS_COL_ERR
 MKL_DSS_NOT_SQUARE
 MKL_DSS_TOO_FEW_VALUES
 MKL_DSS_TOO_MANY_VALUES
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_MSG_LVL_ERR
 MKL_DSS_TERM_LVL_ERR

dss_reorder

Computes or sets a permutation vector that minimizes the fill-in during the factorization phase.

Syntax

C:

```
dss_reorder(handle, opt, perm)
```

Fortran:

```
call dss_reorder(handle, opt, perm)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

If *opt* contains the option MKL_DSS_AUTO_ORDER, then the routine `dss_reorder` computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_METIS_OPENMP_ORDER, then the routine `dss_reorder` computes permutation vector using the parallel (OpenMP) nested dissections algorithm to minimize the fill-in during the factorization phase. This option can be used to decrease the time of `dss_reorder` call on multi-core computers. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_MY_ORDER, then you must supply a permutation vector in the array *perm*. In this case, the array *perm* is of length *nRows*, where *nRows* is the number of rows in the matrix as defined by the previous call to `dss_define_structure`.

If *opt* contains the option `MKL_DSS_GET_ORDER`, then the permutation vector computed during the `dss_reorder` call is copied to the array *perm*. In this case you must allocate the array *perm* beforehand. The permutation vector is computed in the same way as if the option `MKL_DSS_AUTO_ORDER` is set.

Input Parameters

Name	Type	Description
<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Parameter to pass the DSS options. The default value for the permutation type is <code>MKL_DSS_AUTO_ORDER</code> .
<i>perm</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Array of length <i>nRows</i> . Contains a user-defined permutation vector (accessed only if <i>opt</i> contains <code>MKL_DSS_MY_ORDER</code> or <code>MKL_DSS_GET_ORDER</code>).

Output Parameters

Name	Type	Description
<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (<code>MKL_DSS_HANDLE</code>), INTENT(INOUT) C: <code>_MKL_DSS_HANDLE_t*</code>	Pointer to the data structure storing intermediate DSS results (<code>MKL_DSS_HANDLE</code>).

Return Values

`MKL_DSS_SUCCESS`
`MKL_DSS_STATE_ERR`
`MKL_DSS_INVALID_OPTION`
`MKL_DSS_REORDER_ERR`
`MKL_DSS_REORDER1_ERR`
`MKL_DSS_I32BIT_ERR`
`MKL_DSS_FAILURE`
`MKL_DSS_OUT_OF_MEMORY`
`MKL_DSS_MSG_LVL_ERR`
`MKL_DSS_TERM_LVL_ERR`

dss_factor_real, dss_factor_complex

Compute factorization of the matrix with previously specified location of non-zero elements.

Syntax

C:

```
dss_factor_real(handle, opt, rValues)
dss_factor_complex(handle, opt, cValues)
```

Fortran 77:

```
call dss_factor_real(handle, opt, rValues)
call dss_factor_complex(handle, opt, cValues)
```

Fortran 90:**outputtext(unified Fortran 90 interface):**

```
call dss_factor(handle, opt, Values)
```

outputtext(or FORTRAN 77 like interface):

```
call dss_factor_real(handle, opt, rValues)
call dss_factor_complex(handle, opt, cValues)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to `dss_define_structure` and whose non-zero values are given in the array `rValues`, `cValues` or `Values`. Data type These arrays must be of length `nNonZeros` as defined in a previous call to `dss_define_structure`.

NOTE The data type (single or double precision) of `rValues`, `cValues`, `Values` must be in correspondence with precision specified by the parameter `opt` in the routine `dss_create`.

The `opt` argument can contain one of the following options:

- MKL_DSS_POSITIVE_DEFINITE
- MKL_DSS_INDEFINITE
- MKL_DSS_HERMITIAN_POSITIVE_DEFINITE
- MKL_DSS_HERMITIAN_INDEFINITE

depending on your matrix's type.

NOTE This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

Name	Type	Description
<code>handle</code>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (MKL_DSS_HANDLE), INTENT(INOUT) C: _MKL_DSS_HANDLE_t*	Pointer to the data structure storing intermediate DSS results (MKL_DSS_HANDLE).
<code>opt</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Parameter to pass the DSS options. The default value is MKL_DSS_POSITIVE_DEFINITE.

Name	Type	Description
<i>rValues</i>	C: <code>_INTEGER_t const*</code> FORTRAN 77: <code>REAL*4</code> or <code>REAL*8</code> Fortran 90: <code>REAL(KIND=4),</code> <code>INTENT(IN)</code> or <code>REAL(KIND=8), INTENT(IN)</code> C: <code>VOID const*</code>	Array of elements of the matrix <i>A</i> . Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>cValues</i>	FORTRAN 77: <code>COMPLEX*8</code> or <code>COMPLEX*16</code> Fortran 90: <code>COMPLEX(KIND=4),</code> <code>INTENT(IN)</code> or <code>COMPLEX(KIND=8), INTENT(IN)</code> C: <code>VOID const*</code>	Array of elements of the matrix <i>A</i> . Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>Values</i>	Fortran 90: <code>REAL(KIND=4),</code> <code>INTENT(OUT)</code> , or <code>REAL(KIND=8), INTENT(OUT)</code> , or <code>COMPLEX(KIND=4), INTENT(OUT)</code> , or <code>COMPLEX(KIND=8), INTENT(OUT)</code>	Array of elements of the matrix <i>A</i> . Real or complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

Return Values

`MKL_DSS_SUCCESS`
`MKL_DSS_STATE_ERR`
`MKL_DSS_INVALID_OPTION`
`MKL_DSS_OPTION_CONFLICT`
`MKL_DSS_VALUES_ERR`
`MKL_DSS_OUT_OF_MEMORY`
`MKL_DSS_ZERO_PIVOT`
`MKL_DSS_FAILURE`
`MKL_DSS_MSG_LVL_ERR`
`MKL_DSS_TERM_LVL_ERR`
`MKL_DSS_OOC_MEM_ERR`
`MKL_DSS_OOC_OC_ERR`
`MKL_DSS_OOC_RW_ERR`

dss_solve_real, dss_solve_complex

Compute the corresponding solution vector and place it in the output array.

Syntax

C:

```
dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)  
dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Fortran 77:

```
call dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)  
call dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Fortran 90:

outputtext(unified Fortran 90 interface):

```
call dss_solve(handle, opt, RhsValues, nRhs, SolValues)
```

outputtext(or FORTRAN 77 like interface):

```
call dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)  
call dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

For each right hand side column vector defined in the arrays *rRhsValues*, *cRhsValues*, or *RhsValues*, these routines compute the corresponding solution vector and place it in the arrays *rSolValues*, *cSolValues*, or *SolValues* respectively.

NOTE The data type (single or double precision) of all arrays must be in correspondence with precision specified by the parameter *opt* in the routine *dss_create*.

The lengths of the right-hand side and solution vectors, *nCols* and *nRows* respectively, must be defined in a previous call to *dss_define_structure*.

By default, both routines perform the full solution step (it corresponds to *phase* = 33 in PARDISO). The parameter *opt* enables you to calculate the final solution step-by-step, calling forward and backward substitutions.

If it is set to *MKL_DSS_FORWARD_SOLVE*, the forward substitution (corresponding to *phase* = 331 in PARDISO) is performed;

if it is set to *MKL_DSS_DIAGONAL_SOLVE*, the diagonal substitution (corresponding to *phase* = 332 in PARDISO) is performed;

if it is set to *MKL_DSS_BACKWARD_SOLVE*, the backward substitution (corresponding to *phase* = 333 in PARDISO) is performed.

For more details about using these substitutions for different types of matrices, see the [description of the PARDISO solver](#).

This parameter also can control the number of refinement steps that is used on the solution stage: if it is set to `MKL_DSS_REFINEMENT_OFF`, the maximum number of refinement steps equal to zero, and if it is set to `MKL_DSS_REFINEMENT_ON` (default value), the maximum number of refinement steps is equal to 2.

`MKL_DSS_CONJUGATE_SOLVE` option added to the parameter `opt` enables solving a conjugate transposed system $A^H x = b$ based on the factorization of the matrix `A`. This option is equivalent to the parameter `iparm(12) = 1` in PARDISO.

`MKL_DSS_TRANSPOSE_SOLVE` option added to the parameter `opt` enables solving a transposed system $A^T x = b$ based on the factorization of the matrix `A`. This option is equivalent to the parameter `iparm(12) = 2` in PARDISO.

Input Parameters

Name	Type	Description
<code>handle</code>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (<code>MKL_DSS_HANDLE</code>), INTENT(INOUT) C: <code>_MKL_DSS_HANDLE_t*</code>	Pointer to the data structure storing intermediate DSS results (<code>MKL_DSS_HANDLE</code>).
<code>opt</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Parameter to pass the DSS options.
<code>nRhs</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Number of the right-hand sides in the linear equation.
<code>rRhsValues</code>	FORTRAN 77: REAL*4 or REAL*8 Fortran 90: REAL(KIND=4), INTENT(IN) or REAL(KIND=8), INTENT(IN) C: VOID const*	Array of size <code>nRows * nRhs</code> . Contains real right-hand side vectors. Real data, single or double precision as it is specified by the parameter <code>opt</code> in the routine <code>dss_create</code> .
<code>cRhsValues</code>	FORTRAN 77: COMPLEX*8 or COMPLEX*16 Fortran 90: COMPLEX(KIND=4), INTENT(IN) or COMPLEX(KIND=8), INTENT(IN) C: VOID const*	Array of size <code>nRows * nRhs</code> . Contains complex right-hand side vectors. Complex data, single or double precision as it is specified by the parameter <code>opt</code> in the routine <code>dss_create</code> .
<code>RhsValues</code>	Fortran 90: REAL(KIND=4), INTENT(IN), or REAL(KIND=8), INTENT(IN), or COMPLEX(KIND=4), INTENT(IN), or COMPLEX(KIND=8), INTENT(IN)	Array of size <code>nRows * nRhs</code> . Contains right-hand side vectors. Real or complex data, single or double precision as it is specified by the parameter <code>opt</code> in the routine <code>dss_create</code> .

Output Parameters

Name	Type	Description
<i>rSolValues</i>	FORTRAN 77: REAL*4 or REAL*8 Fortran 90: REAL(KIND=4), INTENT(OUT) or REAL(KIND=8), INTENT(OUT) C: VOID const*	Array of size <i>nCols</i> * <i>nRhs</i> . Contains real solution vectors. Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>cSolValues</i>	FORTRAN 77: COMPLEX*8 or COMPLEX*16 Fortran 90: COMPLEX(KIND=4), INTENT(OUT) or COMPLEX(KIND=8), INTENT(OUT) C: VOID const*	Array of size <i>nCols</i> * <i>nRhs</i> . Contains complex solution vectors. Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>SolValues</i>	Fortran 90: REAL(KIND=4), INTENT(OUT), or REAL(KIND=8), INTENT(OUT), or COMPLEX(KIND=4), INTENT(OUT), or COMPLEX(KIND=8), INTENT(OUT)	Array of size <i>nCols</i> * <i>nRhs</i> . Contains solution vectors. Real or complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_DIAG_ERR
 MKL_DSS_FAILURE
 MKL_DSS_MSG_LVL_ERR
 MKL_DSS_TERM_LVL_ERR
 MKL_DSS_OOC_MEM_ERR
 MKL_DSS_OOC_OC_ERR
 MKL_DSS_OOC_RW_ERR

dss_delete

Deletes all of the data structures created during the solutions process.

Syntax

C:

```
dss_delete(handle, opt)
```

Fortran:

```
call dss_delete(handle, opt)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

The routine `dss_delete` deletes all data structures created during the solving process.

Input Parameters

Name	Type	Description
<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: <code>_INTEGER_t const*</code>	Parameter to pass the DSS options. The default value is <code>MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR</code> .

Output Parameters

Name	Type	Description
<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (<code>MKL_DSS_HANDLE</code>), INTENT(INOUT) C: <code>_MKL_DSS_HANDLE_t *</code>	Pointer to the data structure storing intermediate DSS results (<code>MKL_DSS_HANDLE</code>).

Return Values

`MKL_DSS_SUCCESS`
`MKL_DSS_STATE_ERR`
`MKL_DSS_INVALID_OPTION`
`MKL_DSS_OUT_OF_MEMORY`
`MKL_DSS_MSG_LVL_ERR`
`MKL_DSS_TERM_LVL_ERR`

dss_statistics

Returns statistics about various phases of the solving process.

Syntax

C:

```
dss_statistics(handle, opt, statArr, retValues)
```

Fortran:

```
call dss_statistics(handle, opt, statArr, retValues)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90
- C: mkl.h

Description

The dss_statistics routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- duration of problem solving,
- determinant of the input matrix,
- inertia of the input matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter *statArr*. The value of the statistics is returned in double precision in a return array, which you must allocate beforehand.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics can only be requested at the appropriate stages of the solving process. For example, requesting FactorTime before a matrix is factored leads to errors.

The following table shows the point at which each individual statistics item can be requested:

Statistics Calling Sequences

Type of Statistics	When to Call
ReorderTime	After dss_reorder is completed successfully.
FactorTime	After dss_factor_real or dss_factor_complex is completed successfully.
SolveTime	After dss_solve_real or dss_solve_complex is completed successfully.
Determinant	After dss_factor_real or dss_factor_complex is completed successfully.
Inertia	After dss_factor_real is completed successfully and the matrix is real, symmetric, and indefinite.
Flops	After dss_factor_real or dss_factor_complex is completed successfully.
Peakmem	After dss_reorder is completed successfully.
Factormem	After dss_reorder is completed successfully.
Solvemem	After dss_factor_real or dss_factor_complex is completed successfully.

Input Parameters

Name	Type	Description
<i>handle</i>	FORTRAN 77: INTEGER*8 Fortran 90: TYPE (MKL_DSS_HANDLE), INTENT (IN)	Pointer to the data structure storing intermediate DSS results (MKL_DSS_HANDLE).

Name	Type	Description
	C: _MKL_DSS_HANDLE_t*	
<i>opt</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Parameter to pass the DSS options.
	C: _INTEGER_t const*	
<i>statArr</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN)	Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect):
	C: char const*	
	ReorderTime	Amount of time taken to do the reordering.
	FactorTime	Amount of time taken to do the factorization.
	SolveTime	Amount of time taken to solve the problem after factorization.
	Determinant	Determinant of the matrix <i>A</i> . For real matrices: the determinant is returned as <i>det_pow</i> , <i>det_base</i> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_base}) < 10.0$ and <i>determinant</i> = <i>det_base</i> * $10^{(\text{det_pow})}$. For complex matrices: the determinant is returned as <i>det_pow</i> , <i>det_re</i> , <i>det_im</i> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det_re}) + \text{abs}(\text{det_im}) < 10.0$ and <i>determinant</i> = <i>det_re</i> , <i>det_im</i> * $10^{(\text{det_pow})}$.
	Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (<i>p</i> , <i>n</i> , <i>z</i>), where <i>p</i> is the number of positive eigenvalues, <i>n</i> is the number of negative eigenvalues, and <i>z</i> is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations <i>p</i> , <i>n</i> , <i>z</i> . Computing inertia is recommended only for stable matrices. Unstable matrices can lead to incorrect results. Inertia of a <i>k</i> -by- <i>k</i> real symmetric positive definite matrix is always (<i>k</i> , 0, 0). Therefore Inertia is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.
	Flops	Number of floating point operations performed during the factorization.
	Peakmem	Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.

Name	Type	Description
	Factormem	Permanent memory in kilobytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.
	Solvemem	Total double precision memory consumption (kilobytes) of the solver for the factorization and solve phases.

NOTE To avoid problems in passing strings from Fortran to C, Fortran users must call the `mkl_cvt_to_null_terminated_str` routine before calling `dss_statistics`. Refer to the description of `mkl_cvt_to_null_terminated_str` for details.

Output Parameters

Name	Type	Description
<code>retValues</code>	FORTRAN 77: REAL*8 Fortran 90: REAL(KIND=8), INTENT(OUT) C: VOID const*	Value of the statistics returned.

Finding 'time used to reorder' and 'inertia' of a matrix

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics(handle, opt, statArr, retValue)`, where `statArr` is "ReorderTime,Inertia"

In this example, `retValue` has the following values:

<code>retValue[0]</code>	Time to reorder.
<code>retValue[1]</code>	Positive Eigenvalues.
<code>retValue[2]</code>	Negative Eigenvalues.
<code>retValue[3]</code>	Zero Eigenvalues.

Return Values

```
MKL_DSS_SUCCESS
MKL_DSS_INVALID_OPTION
MKL_DSS_STATISTICS_INVALID_MATRIX
MKL_DSS_STATISTICS_INVALID_STATE
MKL_DSS_STATISTICS_INVALID_STRING
MKL_DSS_MSG_LVL_ERR
MKL_DSS_TERM_LVL_ERR
```

[`mkl_cvt_to_null_terminated_str`](#)

Passes character strings from Fortran routines to C routines.

Syntax

```
mkl_cvt_to_null_terminated_str (destStr, destLen, srcStr)
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_dss.f90

Description

The routine `mkl_cvt_to_null_terminated_str` passes character strings from Fortran routines to C routines. The strings are converted into integer arrays before being passed to C. Using this routine avoids the problems that can occur on some platforms when passing strings from Fortran to C. The use of this routine is highly recommended.

Input Parameters

<code>destLen</code>	INTEGER. Length of the output array <code>destStr</code> .
<code>srcStr</code>	STRING. Input string.

Output Parameters

<code>destStr</code>	INTEGER. One-dimensional array of integers.
----------------------	---

Implementation Details

Several aspects of the Intel MKL DSS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, one of the following Intel MKL DSS language-specific header files can be included:

- `mkl_dss.f77` for F77 programs
- `mkl_dss.f90` for F90 programs
- `mkl_dss.h` for C programs

These header files define symbolic constants for returned error values, function options, certain defined data types, and function prototypes.

NOTE Constants for options, returned error values, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel MKL DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

To simplify the use of the Intel MKL DSS routines, they do not require you to allocate any temporary working storage. The solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*.

Each of the Intel MKL DSS routines creates, uses or deletes a handle. Consequently, each program must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that must be used when declaring a handle object in the user code.

Fortran 90 programmers must declare a handle as:

```
INCLUDE "mkl_dss.f90"
```

```
TYPE(MKL_DSS_HANDLE) handle
```

C and C++ programmers must declare a handle as:

```
#include "mkl_dss.h"
_MKL_DSS_HANDLE_t handle;
```

FORTRAN 77 programmers using compilers that support eight byte integers, must declare a handle as:

```
INCLUDE "mkl_dss.f77"
INTEGER*8 handle
```

Otherwise they can replace the INTEGER*8 data types with the DOUBLE PRECISION data type.

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the returned error values
- user options for the solver routines
- constants indicating message severity.

Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel MKL supports the iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as RCI ISS interface . The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI conjugate gradient solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI flexible generalized minimal residual solver, or RCI FGMRES) of linear algebraic equations. This interface uses the general RCI scheme described in [Dong95].

See the [Appendix A Linear Solvers Basics](#) for discussion of terms and concepts related to the ISS routines.

RCI means that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user must perform them and pass the result to the solver. This gives great universality to the solver as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines (see [Sparse BLAS Level 2 and Level 3 Routines](#)).

NOTE The RCI CG solver is implemented in two versions: for system of equations with a single right hand side, and for system of equations with multiple right hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and positive definite.

The FGMRES method may fail if the matrix is degenerate.

Table "RCI CG Interface Routines" lists the names of the routines, and describes their general use.

RCI ISS Interface Routines

Routine	Description
dcg_init , dcgmrhs_init , dfgmres_init	Initializes the solver.
dcg_check , dcgmrhs_check , dfgmres_check	Checks the consistency and correctness of the user defined data.
dcg , dcgmrhs , dfgmres	Computes the approximate solution vector.
dcg_get , dcgmrhs_get , dfgmres_get	Retrieves the number of the current iteration.

The Intel MKL RCI ISS interface routines are normally invoked in this order:

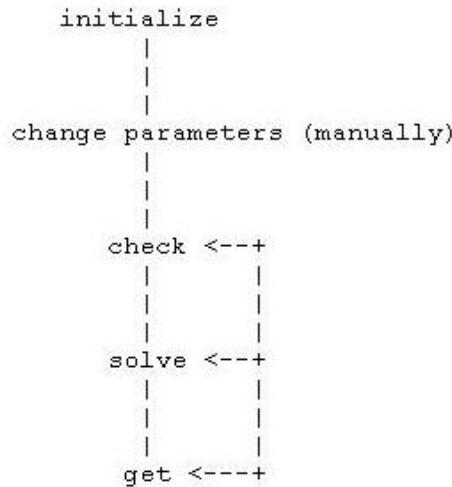

1. <type>_init
2. <type>_check
3. <type>

4. <type>_get

Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram in [Figure "Typical Order for Invoking RCI ISS Interface Routines"](#) indicates the typical order in which the RCI ISS interface routines can be invoked.

[Typical Order for Invoking RCI ISS interface Routines](#)

Code examples that use the RCI ISS interface routines to solve systems of linear equations can be found in the `examples\solver\source` folder of your Intel MKL directory (`cg_no_precon.f`, `cg_no_precon_c.c`, `cg_mrhs.f`, `cg_mrhs_precond.f`, `cg_mrhs_stop_crt.f`, `fgmres_no_precon_f.f`, `fgmres_no_precon_c.c`).

CG Interface Description

All types in this documentation refer to the common Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers should refer to the section [Calling Sparse Solver and Preconditioner Routines from C/C++](#) for information on mapping Fortran types to C/C++ types.

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right hand side (SRHS), and for a system of equations with multiple right hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

Routine Options

All of the RCI CG routines have common parameters for passing various options to the routines (see [CG Common Parameters](#)). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine `dcg` to compute the solution of a system of linear algebraic equations. The Intel MKL RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

CG Common Parameters

NOTE The default and initial values listed below are assigned to the parameters by calling the `dchg_init/dcgmrhs_init` routine.

<i>n</i>	INTEGER, this parameter sets the size of the problem in the <code>dchg_init/dcgmrhs_init</code> routine. All the other routines uses the <code>ipar(1)</code> parameter instead. Note that the coefficient matrix <i>A</i> is a square matrix of size $n \times n$.						
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> for SRHS, or matrix of size (<i>n*nrhs</i>) for MRHS. This parameter contains the current approximation to the solution. Before the first call to the <code>dchg/dcgmrhs</code> routine, it contains the initial approximation to the solution.						
<i>nrhs</i>	INTEGER, this parameter sets the number of right-hand sides for MRHS routines.						
<i>b</i>	DOUBLE PRECISION array containing a single right-hand side vector, or matrix of size (<i>nrhs*n</i>) containing right-hand side vectors.						
<i>RCI_request</i>	INTEGER, this parameter gives information about the result of work of the RCI CG routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <table border="0"> <tr> <td><i>RCI_request</i>= 1</td><td>multiply the matrix by <i>tmp</i> (1:<i>n</i>, 1), put the result in <i>tmp</i>(1:<i>n</i>, 2), and return the control to the <code>dchg/dcgmrhs</code> routine;</td></tr> <tr> <td><i>RCI_request</i>= 2</td><td>to perform the stopping tests. If they fail, return the control to the <code>dchg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <i>x</i> array;</td></tr> <tr> <td><i>RCI_request</i>= 3</td><td>for SRHS: apply the preconditioner to <i>tmp</i>(1:<i>n</i>, 3), put the result in <i>tmp</i>(1:<i>n</i>, 4), and return the control to the <code>dchg</code> routine; for MRHS: apply the preconditioner to <i>tmp</i>(:, 3+<i>ipar</i>(3)), put the result in <i>tmp</i>(:, 3), and return the control to the <code>dcgmrhs</code> routine.</td></tr> </table> Note that the <code>dchg_get/dcgmrhs_get</code> routine does not change the parameter <i>RCI_request</i> . This enables use of this routine inside the <i>reverse communication</i> computations.	<i>RCI_request</i> = 1	multiply the matrix by <i>tmp</i> (1: <i>n</i> , 1), put the result in <i>tmp</i> (1: <i>n</i> , 2), and return the control to the <code>dchg/dcgmrhs</code> routine;	<i>RCI_request</i> = 2	to perform the stopping tests. If they fail, return the control to the <code>dchg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <i>x</i> array;	<i>RCI_request</i> = 3	for SRHS: apply the preconditioner to <i>tmp</i> (1: <i>n</i> , 3), put the result in <i>tmp</i> (1: <i>n</i> , 4), and return the control to the <code>dchg</code> routine; for MRHS: apply the preconditioner to <i>tmp</i> (:, 3+ <i>ipar</i> (3)), put the result in <i>tmp</i> (:, 3), and return the control to the <code>dcgmrhs</code> routine.
<i>RCI_request</i> = 1	multiply the matrix by <i>tmp</i> (1: <i>n</i> , 1), put the result in <i>tmp</i> (1: <i>n</i> , 2), and return the control to the <code>dchg/dcgmrhs</code> routine;						
<i>RCI_request</i> = 2	to perform the stopping tests. If they fail, return the control to the <code>dchg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <i>x</i> array;						
<i>RCI_request</i> = 3	for SRHS: apply the preconditioner to <i>tmp</i> (1: <i>n</i> , 3), put the result in <i>tmp</i> (1: <i>n</i> , 4), and return the control to the <code>dchg</code> routine; for MRHS: apply the preconditioner to <i>tmp</i> (:, 3+ <i>ipar</i> (3)), put the result in <i>tmp</i> (:, 3), and return the control to the <code>dcgmrhs</code> routine.						
<i>ipar</i>	INTEGER array, of size 128 for SRHS, and of size (128+2* <i>nrhs</i>) for MRHS. This parameter specifies the integer set of data for the RCI CG computations: <table border="0"> <tr> <td><i>ipar</i>(1)</td><td>specifies the size of the problem. The <code>dchg_init/dcgmrhs_init</code> routine assigns <i>ipar</i>(1)=<i>n</i>. All the other routines use this parameter instead of <i>n</i>. There is no default value for this parameter.</td></tr> <tr> <td><i>ipar</i>(2)</td><td>specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files <code>dchg_errors.txt</code> and</td></tr> </table>	<i>ipar</i> (1)	specifies the size of the problem. The <code>dchg_init/dcgmrhs_init</code> routine assigns <i>ipar</i> (1)= <i>n</i> . All the other routines use this parameter instead of <i>n</i> . There is no default value for this parameter.	<i>ipar</i> (2)	specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files <code>dchg_errors.txt</code> and		
<i>ipar</i> (1)	specifies the size of the problem. The <code>dchg_init/dcgmrhs_init</code> routine assigns <i>ipar</i> (1)= <i>n</i> . All the other routines use this parameter instead of <i>n</i> . There is no default value for this parameter.						
<i>ipar</i> (2)	specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files <code>dchg_errors.txt</code> and						

`dcg_check_warnings.txt`, respectively. Note that if `ipar(6)` and `ipar(7)` parameters are set to 0, error and warning messages are not generated at all.

`ipar(3)`

for SRHS: contains the current stage of the RCI CG computations. The initial value is 1;
for MRHS: contains the right-hand side for which the calculations are currently performed.

WARNING Avoid altering this variable during computations.

`ipar(4)`

contains the current iteration number. The initial value is 0.

`ipar(5)`

specifies the maximum number of iterations. The default value is `min(150, n)`.

`ipar(6)`

if the value is not equal to 0, the routines output error messages in accordance with the parameter `ipar(2)`. Otherwise, the routines do not output error messages at all, but return a negative value of the parameter `RCI_request`. The default value is 1.

`ipar(7)`

if the value is not equal to 0, the routines output warning messages in accordance with the parameter `ipar(2)`. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter `RCI_request`. The default value is 1.

`ipar(8)`

if the value is not equal to 0, the `dkg/dcgmrhs` routine performs the stopping test for the maximum number of iterations: $ipar(4) \leq ipar(5)$. Otherwise, the method is stopped and the corresponding value is assigned to the `RCI_request`. If the value is 0, the routine does not perform this stopping test. The default value is 1.

`ipar(9)`

if the value is not equal to 0, the `dkg/dcgmrhs` routine performs the residual stopping test:

$dpar(5) \leq dpar(4) = dpar(1) * dpar(3) + dpar(2)$. Otherwise, the method is stopped and corresponding value is assigned to the `RCI_request`. If the value is 0, the routine does not perform this stopping test. The default value is 0.

`ipar(10)`

if the value is not equal to 0, the `dkg/dcgmrhs` routine requests a user-defined stopping test by setting the output parameter `RCI_request=2`. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

NOTE At least one of the parameters `ipar(8)` - `ipar(10)` must be set to 1.

ipar(11)

if the value is equal to 0, the `dcg/dcgmrhs` routine runs the non-preconditioned version of the corresponding CG method. Otherwise, the routine runs the preconditioned version of the CG method, and by setting the output parameter `RCI_request=3`, indicates that you must perform the preconditioning step. The default value is 0.

*ipar(11:128),
ipar(11:128+2*nrhs
s)*

are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE You must declare the array `ipar` with length 128. While defining the array in the code using RCI CG SRHS as INTEGER `ipar(11)` works, there is no guarantee of future compatibility with Intel MKL.

dpar

DOUBLE PRECISION array, for SRHS of size 128, for MRHS of size $(128+2*nrhs)$; this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

dpar(1)

specifies the relative tolerance. The default value is 1.0D-6.

dpar(2)

specifies the absolute tolerance. The default value is 0.0D-0.

dpar(3)

specifies the square norm of the initial residual (if it is computed in the `dcg/dcgmrhs` routine). The initial value is 0.

dpar(4)

service variable equal to $dpar(1)*dpar(3)+dpar(2)$ (if it is computed in the `dcg/dcgmrhs` routine). The initial value is 0.

dpar(5)

- specifies the square norm of the current residual. The initial value is 0.0.

dpar(6)

specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.

dpar(7)

contains the *alpha* parameter of the CG method. The initial value is 0.0.

dpar(8)

contains the *beta* parameter of the CG method, it is equal to $dpar(5)/dpar(6)$. The initial value is 0.0.

dpar(9:128),

*dpar(9:128+2*nrhs
)*

are reserved and not used in the current RCI CG SRHS and MRHS routines respectively.

NOTE You must declare the array `dpar` with length 128. While defining the array in the code using RCI CG SRHS as DOUBLE PRECISION `dpar(8)` works, there is no guarantee of future compatibility with Intel MKL.

tmp

DOUBLE PRECISION array of size $(n, 4)$ for SRHS, and $(n, 3+nrhs)$ for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

$tmp(:, 1)$	specifies the current search direction. The initial value is 0.0.
$tmp(:, 2)$	contains the matrix multiplied by the current search direction. The initial value is 0.0.
$tmp(:, 3)$	contains the current residual. The initial value is 0.0.
$tmp(:, 4)$	contains the inverse of the preconditioner applied to the current residual. There is no initial value for this parameter.

 **NOTE** You can define this array in the code using RCI CG SRHS as DOUBLE PRECISION $tmp(n, 3)$ if you run only non-preconditioned CG iterations.

Schemes of Using the RCI CG Routines

The following pseudocode shows the general schemes of using the RCI CG routines.

```

...
generate matrix A
generate preconditioner C (optional)
call dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
change parameters in ipar, dpar if necessary
call dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)
1 call dcg(n, x, b, RCI_request, ipar, dpar, tmp)
if (RCI_request.eq.1) then
  multiply the matrix A by  $tmp(1:n, 1)$  and put the result in  $tmp(1:n, 2)$ 
It is possible to use MKL Sparse BLAS Level 2 subroutines for this operation
c proceed with CG iterations
  goto 1
endif
if (RCI_request.eq.2) then
  do the stopping test
  if (test not passed) then
c proceed with CG iterations
    go to 1
  else
c stop CG iterations
    goto 2
  endif
endif
if (RCI_request.eq.3) then (optional)
  apply the preconditioner C inverse to  $tmp(1:n, 3)$  and put the result in  $tmp(1:n, 4)$ 

```

```

c proceed with CG iterations
goto 1
end

2 call dcg_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
current iteration number is in itercount
the computed approximation is in the array x

```

FGMRES Interface Description

All types in this documentation refer to the common Fortran types, INTEGER, and DOUBLE PRECISION.

C and C++ programmers should refer to the section [Calling Sparse Solver and Preconditioner Routines from C/C++](#) for information on mapping Fortran types to C/C++ types.

Routine Options

All of the RCI FGMRES routines have common parameters for passing various options to the routines (see [FGMRES Common Parameters](#)). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfrmres` to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL RCI FGMRES routines do not make copies of the user input arrays.

FGMRES Common Parameters

NOTE The default and initial values listed below are assigned to the parameters by calling the `dfrmres_init` routine.

<i>n</i>	INTEGER, this parameter sets the size of the problem in the <code>dfrmres_init</code> routine. All the other routines uses <code>ipar(1)</code> parameter instead. Note that the coefficient matrix <code>A</code> is a square matrix of size $n \times n$.
<i>x</i>	DOUBLE PRECISION array, this parameter contains the current approximation to the solution vector. Before the first call to the <code>dfrmres</code> routine, it contains the initial approximation to the solution vector.
<i>b</i>	DOUBLE PRECISION array, this parameter contains the right-hand side vector. Depending on user requests (see the parameter <code>ipar(13)</code> , it may later contain the approximate solution.
<i>RCI_request</i>	INTEGER, this parameter gives information about the result of work of the RCI FGMRES routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <code>RCI_request= 1</code> multiply the matrix by <code>tmp(ipar(22))</code> , put the result in <code>tmp(ipar(23))</code> , and return the control to the <code>dfrmres</code> routine;

<i>RCI_request</i> = 2	perform the stopping tests. If they fail, return the control to the <code>dfgres</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine;
<i>RCI_request</i> = 3	apply the preconditioner to <code>tmp(ipar(22))</code> , put the result in <code>tmp(ipar(23))</code> , and return the control to the <code>dfgmres</code> routine.
<i>RCI_request</i> = 4	check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the <code>dfgmres</code> routine if it is not zero, otherwise complete the solution process by calling <code>dfgmres_get</code> routine.
<i>ipar</i> (128)	INTEGER array, this parameter specifies the integer set of data for the RCI FGMRES computations:
<i>ipar</i> (1)	specifies the size of the problem. The <code>dfgmres_init</code> routine assigns <i>ipar</i> (1)= <i>n</i> . All the other routines uses this parameter instead of <i>n</i> . There is no default value for this parameter.
<i>ipar</i> (2)	specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file <code>MKL_RCI_FGMRES_Log.txt</code> . Note that if <i>ipar</i> (6) and <i>ipar</i> (7) parameters are set to 0, error and warning messages are not generated at all.
<i>ipar</i> (3)	contains the current stage of the RCI FGMRES computations., The initial value is 1.
 WARNING Avoid altering this variable during computations.	
<i>ipar</i> (4)	contains the current iteration number. The initial value is 0.
<i>ipar</i> (5)	specifies the maximum number of iterations. The default value is <code>min(150,n)</code> .
<i>ipar</i> (6)	if the value is not 0, the routines output error messages in accordance with the parameter <i>ipar</i> (2). If it is 0, the routines do not output error messages at all, but return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> (7)	if the value is not 0, the routines output warning messages in accordance with the parameter <i>ipar</i> (2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter <i>RCI_request</i> . The default value is 1.

ipar(8)

if the value is not equal to 0, the `dfmres` routine performs the stopping test for the maximum number of iterations: $ipar(4) \leq ipar(5)$. If the value is 0, the `dfgmres` routine does not perform this stopping test. The default value is 1.

ipar(9)

if the value is not 0, the `dfgmres` routine performs the residual stopping test: $dpar(5) \leq dpar(4)$. If the value is 0, the `dfgmres` routine does not perform this stopping test. The default value is 0.

ipar(10)

if the value is not 0, the `dfgmres` routine indicates that the user-defined stopping test be performed by setting `RCI_request=2`. If the value is 0, the `dfgmres` routine does not perform the user-defined stopping test. The default value is 1.

 **NOTE** At least one of the parameters *ipar(8)* - *ipar(10)* must be set to 1.

ipar(11)

if the value is 0, the `dfgmres` routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests that you perform the preconditioning step by setting the output parameter `RCI_request=3`. The default value is 0.

ipar(12)

if the value is not equal to 0, the `dfgmres` routine performs the automatic test for zero norm of the currently generated vector: $dpar(7) \leq dpar(8)$, where `dpar(8)` contains the tolerance value. Otherwise, the routine indicates that you must perform this check by setting the output parameter `RCI_request=4`. The default value is 0.

ipar(13)

if the value is equal to 0, the `dfgmres_get` routine updates the solution to the vector `x` according to the computations done by the `dfgmres` routine. If the value is positive, the routine writes the solution to the right hand side vector `b`. If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0.

NOTE It is possible to call the `dfgmres_get` routine at any place in the code, but you must pay special attention to the parameter `ipar(13)`. The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter `ipar(13)` is not equal to zero. If `ipar(13)` is positive, then the updated solution overwrites the right hand side in the vector `b`. If you want to run the restarted version of FGMRES with the same right hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive `ipar(13)`.

`ipar(14)`

contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

WARNING Do not alter this variable during computations.

`ipar(15)`

specifies the number of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, assign the number of iterations to `ipar(15)` before the restart. The default value is `min(150, n)`, which means that by default the non-restarted version of FGMRES method is used.

`ipar(16)`

service variable specifying the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see [Matrix Arguments](#) in the Appendix B for details) is started in the `tmp` array.

`ipar(17)`

service variable specifying the location of the rotation cosines from which the vector of cosines is started in the `tmp` array.

`ipar(18)`

service variable specifying the location of the rotation sines from which the vector of sines is started in the `tmp` array.

`ipar(19)`

service variable specifying the location of the rotated residual vector from which the vector is started in the `tmp` array.

`ipar(20)`

service variable, specifies the location of the least squares solution vector from which the vector is started in the `tmp` array.

`ipar(21)`

service variable specifying the location of the set of preconditioned vectors from which the set is started in the `tmp` array. The memory locations in the `tmp` array starting from `ipar(21)` are used only for the preconditioned FGMRES method.

ipar(22)

specifies the memory location from which the first vector (source) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(23)

specifies the memory location from which the second vector (source) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(24:128)

are reserved and not used in the current RCI FGMRES routines.

NOTE You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER *ipar*(23) works, there is no guarantee of future compatibility with Intel MKL.

dpar(128)

DOUBLE PRECISION array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:

dpar(1)

specifies the relative tolerance. The default value is 1.0D-6.

dpar(2)

specifies the absolute tolerance. The default value is 0.0D-0.

dpar(3)

specifies the Euclidean norm of the initial residual (if it is computed in the *dfgmres* routine). The initial value is 0.0.

dpar(4)

service variable equal to *dpar*(1) **dpar*(3) +*dpar*(2) (if it is computed in the *dfgmres* routine). The initial value is 0.0.

dpar(5)

specifies the Euclidean norm of the current residual. The initial value is 0.0.

dpar(6)

specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.

dpar(7)

contains the norm of the generated vector. The initial value is 0.0.

NOTE In terms of [Saad03] this parameter is the coefficient $h_{k+1,k}$ of the Hessenberg matrix.

dpar(8)

contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0D-12.

dpar(9:128)

are reserved and not used in the current RCI FGMRES routines.

NOTE You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION *dpar*(8) works, there is no guarantee of future compatibility with Intel MKL.

<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n + ipar(15)*(ipar(15)+9)/2 + 1)$ used to supply the double precision temporary space for the RCI FGMRES computations, specifically:
<i>tmp(1:ipar(16)-1)</i>	contains the sequence of vectors generated by the FGMRES method. The initial value is 0.0.
<i>tmp(ipar(16):ipar(17)-1)</i>	contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of <i>tmp</i> array.
<i>tmp(ipar(17):ipar(18)-1)</i>	contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp(ipar(18):ipar(19)-1)</i>	contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp(ipar(19):ipar(20)-1)</i>	contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp(ipar(20):ipar(21)-1)</i>	contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of <i>tmp</i> array.
<i>tmp(ipar(21):)</i>	contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of <i>tmp</i> array is not used if the non-preconditioned version of FGMRES method is called. There is no initial value for this part of <i>tmp</i> array.

NOTE You can define this array in the code as
DOUBLE PRECISION *tmp*((2*ipar(15)+1)*n +
ipar(15)*(ipar(15)+9)/2 + 1)) if you run
only non-preconditioned FGMRES iterations.

Schemes of Using the RCI FGMRES Routines

The following pseudocode shows the general schemes of using the RCI FGMRES routines.

...

generate matrix *A*

generate preconditioner *C* (optional)

```
call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
change parameters in ipar, dpar if necessary
call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1 call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
if (RCI_request.eq.1) then
    multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
```

It is possible to use **MKL Sparse BLAS Level 2** subroutines for this operation

c proceed with FGMRES iterations

goto 1

```

endif

if (RCI_request.eq.2) then
  do the stopping test
  if (test not passed) then
    c proceed with FGMRES iterations
      go to 1
    else
      c stop FGMRES iterations
        goto 2
    endif
  endif
  if (RCI_request.eq.3) then (optional)
    apply the preconditioner C inverse to tmp(ipar(22)) and put the result in tmp(ipar(23))
  c proceed with FGMRES iterations
    goto 1
  endif
  if (RCI_request.eq.4) then
    check the norm of the next orthogonal vector, it is contained in dpar(7)
    if (the norm is not zero up to rounding/computational errors) then
      c proceed with FGMRES iterations
        goto 1
      else
        c stop FGMRES iterations
          goto 2
      endif
    endif
  2 call dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
  current iteration number is in itercount
  the computed approximation is in the array x

```

NOTE For the FGMRES method, the array *x* initially contains the current approximation to the solution. It can be updated only by calling the routine `dfgmres_get`, which updates the solution in accordance with the computations performed by the routine `dfgmres`.

The above pseudocode demonstrates two main differences in the use of RCI FGMRES interface comparing with the [CG Interface Description](#). The first difference relates to `RCI_request=3`: it uses different locations in the `tmp` array, which is two-dimensional for CG and one-dimensional for FGMRES. The second difference relates to `RCI_request=4`: the RCI CG interface never produces `RCI_request=4`.

RCI ISS Routines

dcg_init

Initializes the solver.

Syntax

```
dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel MKL RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set these parameters directly in the appropriate routines.

WARNING You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem.
<code>x</code>	DOUBLE PRECISION array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
<code>b</code>	DOUBLE PRECISION array of size n . Contains the right-hand side vector.

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about the result of the routine.
<code>ipar</code>	INTEGER array of size 128. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request= 0</code>	Indicates that the task completed normally.
<code>RCI_request= -10000</code>	Indicates failure to complete the task.

dcg_check

Checks consistency and correctness of the user defined data.

Syntax

```
dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the solver returns the correct result. It only reduces the chance of making a mistake in the parameters of the method. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem.
<code>x</code>	DOUBLE PRECISION array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <code>b</code> .
<code>b</code>	DOUBLE PRECISION array of size n . Contains the right-hand side vector.

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about result of the routine.
<code>ipar</code>	INTEGER array of size 128. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request= 0</code>	Indicates that the task completed normally.
<code>RCI_request= -1100</code>	Indicates that the task is interrupted and the errors occur.
<code>RCI_request= -1001</code>	Indicates that there are some warning messages.
<code>RCI_request= -1010</code>	Indicates that the routine changed some parameters to make them consistent or correct.
<code>RCI_request= -1011</code>	Indicates that there are some warning messages and that the routine changed some parameters.

dcg

Computes the approximate solution vector.

Syntax

```
dcg(n, x, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The `dcg` routine computes the approximate solution vector using the CG method [Young71]. The routine `dcg` uses the vector in the array `x` before the first call as an initial approximation to the solution. The parameter `RCI_request` gives you information about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem.
<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the initial approximation to the solution vector.
<code>b</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the right-hand side vector.
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about result of work of the routine.
<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the updated approximation to the solution vector.
<code>ipar</code>	INTEGER array of size 128. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 4)$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request=0</code>	Indicates that the task completed normally and the solution is found and stored in the vector <code>x</code> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <code>RCI_request= 2</code> .
<code>RCI_request=-1</code>	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<code>RCI_request=-2</code>	Indicates that the routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<code>RCI_request=- 10</code>	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <code>dpar(6)</code> was altered outside of the routine, or the <code>dcg_check</code> routine was not called.
<code>RCI_request=-11</code>	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <code>ipar(8), ipar(9), ipar(10)</code> were altered outside of the routine, or the <code>dcg_check</code> routine was not called.
<code>RCI_request= 1</code>	Indicates that you must multiply the matrix by <code>tmp(1:n, 1)</code> , put the result in the <code>tmp(1:n, 2)</code> , and return the control back to the routine <code>dcg</code> .

<i>RCI_request</i> = 2	Indicates that you must perform the stopping tests. If they fail, return control back to the <code>drg</code> routine. Otherwise, the solution is found and stored in the vector <i>x</i> .
<i>RCI_request</i> = 3	Indicates that you must apply the preconditioner to <i>tmp</i> (:, 3), put the result in the <i>tmp</i> (:, 4), and return the control back to the routine <code>drg</code> .

dcg_get

Retrieves the number of the current iteration.

Syntax

```
dcg_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcg_get` retrieves the current iteration number of the solutions process.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation vector to the solution.
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.
<i>RCI_request</i>	INTEGER. This parameter is not used.
<i>ipar</i>	INTEGER array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size (<i>n</i> , 4). Refer to the CG Common Parameters .

Output Parameters

<i>itercount</i>	INTEGER argument. Returns the current iteration number.
------------------	---

Return Values

The routine `dcg_get` has not return values.

dcgmrhs_init

Initializes the RCI CG solver with MHRs.

Syntax

```
dcgmrhs_init(n, x, nrhs, b, method, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel MKL RCI CG with multiple right hand sides (MRHS) routines use the values of all parameters that are returned by `dcmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

 **WARNING** You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcmrhs_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem.
<code>x</code>	DOUBLE PRECISION matrix of size $n \times nrhs$. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <code>b</code> .
<code>nrhs</code>	INTEGER. Sets the number of right-hand sides.
<code>b</code>	DOUBLE PRECISION matrix of size $nrhs \times n$. Contains the right-hand side vectors.
<code>method</code>	INTEGER. Specifies the method of solution: A value of 1 indicates CG with multiple right hand sides (default value)

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about the result of the routine.
<code>ipar</code>	INTEGER array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request= 0</code>	Indicates that the task completed normally.
<code>RCI_request= -10000</code>	Indicates failure to complete the task.

`dcmrhs_check`

Checks consistency and correctness of the user defined data.

Syntax

```
dcmrhs_check(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcmrhs_check` checks the consistency and correctness of the parameters to be passed to the solver routine `dcmrhs`. While this operation reduces the chance of making a mistake in the parameters, it does not guarantee that the solver returns the correct result.

If you are sure that the correct data is *specified* in the solver parameters, you can skip this operation.

The lengths of all vectors must be defined in a previous call to the `dcmrhs_init` routine.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem.
<code>x</code>	DOUBLE PRECISION matrix of size $n \times nrhs$. THAT IS TEST Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to b .
<code>nrhs</code>	INTEGER. This parameter sets the number of right-hand sides.
<code>b</code>	DOUBLE PRECISION matrix of size $(nrhs, n)$. Contains the right-hand side vectors.

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about the results of the routine.
<code>ipar</code>	INTEGER array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request= 0</code>	Indicates that the task completed normally.
<code>RCI_request= -1100</code>	Indicates that the task is interrupted and the errors occur.
<code>RCI_request= -1001</code>	Indicates that there are some warning messages.
<code>RCI_request= -1010</code>	Indicates that the routine changed some parameters to make them consistent or correct.
<code>RCI_request= -1011</code>	Indicates that there are some warning messages and that the routine changed some parameters.

dcmrhs

Computes the approximate solution vectors.

Syntax

```
dcmrhs(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcmrhs` computes approximate solution vectors using the CG with multiple right hand sides (MRHS) method [Young71]. The routine `dcmrhs` uses the value that was in the `x` before the first call as an initial approximation to the solution. The parameter `RCI_request` gives information about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcmrhs_init` routine.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem, and the sizes of arrays <code>x</code> and <code>b</code> .
<code>x</code>	DOUBLE PRECISION matrix of size $n \times nrhs$. Contains the initial approximation to the solution vectors.
<code>nrhs</code>	INTEGER. Sets the number of right-hand sides.
<code>b</code>	DOUBLE PRECISION matrix of size $(nrhs \times n)$. Contains the right-hand side vectors.
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about result of work of the routine.
<code>x</code>	DOUBLE PRECISION matrix of size n -by- $nrhs$. Contains the updated approximation to the solution vectors.
<code>ipar</code>	INTEGER array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request=0</code>	Indicates that the task completed normally and the solution is found and stored in the vector <code>x</code> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <code>RCI_request= 2</code> .
<code>RCI_request=-1</code>	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if both tests are requested by the user.
<code>RCI_request=-2</code>	The routine was interrupted because an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<code>RCI_request=- 10</code>	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <code>dpar(6)</code> was altered outside of the routine, or the <code>dmg_check</code> routine was not called.
<code>RCI_request=-11</code>	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <code>ipar(8), ipar(9), ipar(10)</code> were altered outside of the routine, or the <code>dmg_check</code> routine was not called.

<i>RCI_request</i> = 1	Indicates that you must multiply the matrix by $\text{tmp}(1:n, 1)$, put the result in the $\text{tmp}(1:n, 2)$, and return the control back to the routine <code>dcg</code> .
<i>RCI_request</i> = 2	Indicates that you must perform the stopping tests. If they fail, return control back to the <code>dcg</code> routine. Otherwise, the solution is found and stored in the vector x .
<i>RCI_request</i> = 3	Indicates that you must apply the preconditioner to $\text{tmp}(:, 3)$, put the result in the $\text{tmp}(:, 4)$, and return the control back to the routine <code>dcg</code> .

dcgmrhs_get

Retrieves the number of the current iteration.

Syntax

```
dcgmrhs_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcgmrhs_get` retrieves the current iteration number of the solving process.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION matrix of size $n*nrhs$. Contains the initial approximation to the solution vectors.
<i>nrhs</i>	INTEGER. Sets the number of right-hand sides.
<i>b</i>	DOUBLE PRECISION matrix of size $(nrhs, n)$. Contains the right-hand side .
<i>RCI_request</i>	INTEGER. This parameter is not used.
<i>ipar</i>	INTEGER array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Output Parameters

<i>itercount</i>	INTEGER array of size $(nrhs)$. Returns the current iteration number for each right-hand side.
------------------	---

Return Values

The routine `dcgmrhs_get` has no return values.

dfgmres_init

Initializes the solver.

Syntax

```
dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel MKL RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

 **WARNING** You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem.
<code>x</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <code>b</code> .
<code>b</code>	DOUBLE PRECISION array of size <code>n</code> . Contains the right-hand side vector.

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about the result of the routine.
<code>ipar</code>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size ((2* <code>ipar</code> (15) + 1)* <code>n</code> + <code>ipar</code> (15)*(<code>ipar</code> (15) + 9)/2 + 1). Refer to the FGMRES Common Parameters .

Return Values

<code>RCI_request</code> = 0	Indicates that the task completed normally.
<code>RCI_request</code> = -10000	Indicates failure to complete the task.

dfgmres_check

Checks consistency and correctness of the user defined data.

Syntax

```
dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine `dfgmres_check` checks consistency and correctness of the parameters to be passed to the solver routine `dfgmres`. However, this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the routine. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

Input Parameters

<code>n</code>	INTEGER. Sets the size of the problem.
<code>x</code>	DOUBLE PRECISION array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
<code>b</code>	DOUBLE PRECISION array of size n . Contains the right-hand side vector.

Output Parameters

<code>RCI_request</code>	INTEGER. Gives information about result of the routine.
<code>ipar</code>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<code>dpar</code>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<code>tmp</code>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n + ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<code>RCI_request = 0</code>	Indicates that the task completed normally.
<code>RCI_request = -1100</code>	Indicates that the task is interrupted and the errors occur.
<code>RCI_request = -1001</code>	Indicates that there are some warning messages.
<code>RCI_request = -1010</code>	Indicates that the routine changed some parameters to make them consistent or correct.
<code>RCI_request = -1011</code>	Indicates that there are some warning messages and that the routine changed some parameters.

dfgmres

Makes the FGMRES iterations.

Syntax

```
dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dfgmres` performs the FGMRES iterations [Saad03], using the value that was in the array `x` before the first call as an initial approximation of the solution vector. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter `ipar(13)` is not equal to 0 (default value). Note that the updated solution overwrites the right hand side in the vector `b` if the parameter

ipar(13) is positive, and the restarted version of the FGMRES method can not be run. If you want to keep the right hand side, you must save it in a different memory location before the first call to the dfgmres_get routine with a positive *ipar*(13).

The parameter *RCI_request* gives information about the task completion and requests results of certain operations that the solver requires.

The lengths of all the vectors must be defined in a previous call to the dfgmres_init routine.

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the initial approximation to the solution vector.
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . Contains the right-hand side vector.
<i>tmp</i>	DOUBLE PRECISION array of size ((2* <i>ipar</i> (15)+1)* <i>n</i> + <i>ipar</i> (15)* <i>ipar</i> (15)+9)/2 + 1). Refer to the FGMRES Common Parameters .

Output Parameters

<i>RCI_request</i>	INTEGER. Informs about result of work of the routine.
<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size ((2* <i>ipar</i> (15)+1)* <i>n</i> + <i>ipar</i> (15)* <i>ipar</i> (15)+9)/2 + 1). Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> =0	Indicates that the task completed normally and the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <i>RCI_request</i> = 2 or 4.
<i>RCI_request</i> =-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<i>RCI_request</i> = -10	Indicates that the routine was interrupted because of an attempt to divide by zero. Usually this happens if the matrix is degenerate or almost degenerate. However, it may happen if the parameter <i>dpar</i> is altered, or if the method is not stopped when the solution is found.
<i>RCI_request</i> = -11	Indicates that the routine was interrupted because it entered an infinite cycle. Usually this happens because the values <i>ipar</i> (8), <i>ipar</i> (9), <i>ipar</i> (10) were altered outside of the routine, or the dfgmres_check routine was not called.
<i>RCI_request</i> = -12	Indicates that the routine was interrupted because errors were found in the method parameters. Usually this happens if the parameters <i>ipar</i> and <i>dpar</i> were altered by mistake outside the routine.

<i>RCI_request</i> = 1	Indicates that you must multiply the matrix by <i>tmp(ipar(22))</i> , put the result in the <i>tmp(ipar(23))</i> , and return the control back to the routine <i>dfgmres</i> .
<i>RCI_request</i> = 2	Indicates that you must perform the stopping tests. If they fail, return control to the <i>dfgmres</i> routine. Otherwise, the FGMRES solution is found, and you can run the <i>fgmres_get</i> routine to update the computed solution in the vector <i>x</i> .
<i>RCI_request</i> = 3	Indicates that you must apply the inverse preconditioner to <i>ipar(22)</i> , put the result in the <i>ipar(23)</i> , and return the control back to the routine <i>dfgmres</i> .
<i>RCI_request</i> = 4	Indicates that you must check the norm of the currently generated vector. If it is not zero within the computational/rounding errors, return control to the <i>dfgmres</i> routine. Otherwise, the FGMRES solution is found, and you can run the <i>dfgmres_get</i> routine to update the computed solution in the vector <i>x</i> .

dfgmres_get

Retrieves the number of the current iteration and updates the solution.

Syntax

`dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dfgmres_get` retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the `dfgmres` routine. To retrieve the current iteration number only, set the parameter *ipar(13) = -1* beforehand. Normally, you should do this before proceeding further with the computations. If the intermediate solution is needed, the method parameters must be set properly. For details see [FGMRES Common Parameters](#) and the Iterative Sparse Solver code examples in the `examples\solver\source` folder of your Intel MKL directory (`cg_no_precon.f`, `cg_no_precon_c.c`, `cg_mrhs.f`, `cg_mrhs_precond.f`, `cg_mrhs_stop_crt.f`, `fgmres_no_precon_f.f`, `fgmres_no_precon_c.c`).

Input Parameters

<i>n</i>	INTEGER. Sets the size of the problem.
<i>ipar</i>	INTEGER array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	DOUBLE PRECISION array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	DOUBLE PRECISION array of size $((2*ipar(15)+1)*n + ipar(15)*ipar(15)+9)/2 + 1$. Refer to the FGMRES Common Parameters .

Output Parameters

<i>x</i>	DOUBLE PRECISION array of size <i>n</i> . If <i>ipar</i> (13) = 0, it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<i>b</i>	DOUBLE PRECISION array of size <i>n</i> . If <i>ipar</i> (13) > 0, it contains the updated approximation to the solution according to the computations done in <code>dfgmres</code> routine. Otherwise, it is not changed.
<i>RCI_request</i>	INTEGER. Gives information about result of the routine.
<i>iitercount</i>	INTEGER argument. Contains the value of the current iteration number.

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -12	Indicates that the routine was interrupted because errors were found in the routine parameters. Usually this happens if the parameters <i>ipar</i> and <i>dpar</i> are altered by mistake outside of the routine.
<i>RCI_request</i> = -10000	Indicates that the routine failed to complete the task.

Implementation Details

Several aspects of the Intel MKL RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel MKL RCI ISS language-specific header files.

The C-language header file defines these function prototypes:

```
void dcg_init(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);

void dcg_check(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);

void dcg(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar, double
*tmp);

void dcg_get(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp, int *iitercount);

void dcgmrhs_init(int *n, double *x, int *nRhs, double *b, int *method, int
*rci_request, int *ipar, double dpar, double *tmp);

void dcgmrhs_check(int *n, double *x, int *nRhs, double *b, int *rci_request, int
*ipar, double dpar, double *tmp);

void dcgmrhs(int *n, double *x, int *nRhs, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);

void dcgmrhs_get(int *n, double *x, int *nRhs, double *b, int *rci_request, int *ipar,
double dpar, double *tmp, int *iitercount);

void dfgmres_init(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp);

void dfgmres_check(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp);

void dfgmres(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);
```

```
void dfgmres_get(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp, int *itercount);
```

NOTE Intel MKL does not support the RCI ISS interface unless you include the language-specific header file.

Preconditioners based on Incomplete LU Factorization Technique

Preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms *preconditioner* and *accelerator* are synonyms, hereafter only *preconditioner* is used.

Intel MKL provides two preconditioners, ILU0 and ILUT, for sparse matrices presented in the format accepted in the Intel MKL direct sparse solvers (three-array variation of the CSR storage format described in [Sparse Matrix Storage Format](#)). The used algorithms used are described in [Saad03].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: lower and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT algorithm is that it calculates each element of the preconditioner and saves each one if it satisfies two conditions simultaneously: its value is greater than the product of the given tolerance and matrix row norm, and its value is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel MKL RCI FGMRES solver (see [Sparse Solver Routines](#)). Avoid using these preconditioners with MKL RCI CG solver because in general, they produce a non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel MKL triangular solver routine `mkl_dcsrtrs` must be applied twice: for the lower triangular part of the preconditioner, and then for its upper triangular part.

NOTE Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. Whether or not the preconditioner produces an acceptable result can only be determined in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial solution, and even ruin the convergence. It is your responsibility as a user to choose a suitable preconditioner.

General Scheme of Using ILUT and RCI FGMRES Routines

The general scheme for use is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. You can see all these differences in the code examples for both preconditioners in the `examples\solver\source` folder of your Intel MKL directory (`dcsrilu0_exampl1.c`, `dcsrilu0_exampl2.f`, `dcsrilut_exampl1.c`, `dcsrilut_exampl2.f`).

The following pseudocode shows the general scheme of using the ILUT preconditioner in the RCI FGMRES context.

...

generate matrix A

generate preconditioner C (optional)

```
call dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)
```

```

change parameters in ipar, dpar if necessary

call dcsrilut(n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1 call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
if (RCI_request.eq.1) then
    multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
c proceed with FGMRES iterations
    goto 1
endif
if (RCI_request.eq.2) then
    do the stopping test
    if (test not passed) then
c proceed with FGMRES iterations
        go to 1
    else
c stop FGMRES iterations.
        goto 2
    endif
endif
if (RCI_request.eq.3) then
c Below, trvec is an intermediate vector of length at least n
c Here is the recommended use of the result produced by the ILUT routine.
c via standard Intel MKL Sparse Blas solver routine mkl_dcsrtrsv.
    call mkl_dcsrtrsv('L','N','U', n, bilut, ibilut, jbilut, tmp(ipar(22)),trvec)
    call mkl_dcsrtrsv('U','N','N', n, bilut, ibilut, jbilut, trvec, tmp(ipar(23)))
c proceed with FGMRES iterations
    goto 1
endif
if (RCI_request.eq.4) then
    check the norm of the next orthogonal vector, it is contained in dpar(7)
    if (the norm is not zero up to rounding/computational errors) then
c proceed with FGMRES iterations
        goto 1
    else
c stop FGMRES iterations
        goto 2
    endif

```

```
endif  
2 call dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)  
current iteration number is in itercount  
the computed approximation is in the array x
```

ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel MKL preconditioner routines are discussed in the [Appendix A Linear Solvers Basics](#).

In this section the FORTRAN style notations are used. All types refer to the standard Fortran types, INTEGER, and DOUBLE PRECISION.

C and C++ programmers must refer to the section [Calling Sparse Solver and Preconditioner Routines from C C++](#) for information on mapping Fortran types to C/C++ types.

User Data Arrays

The preconditioner routines take arrays of user data as input. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL preconditioner routines do not make copies of the user input arrays.

Common Parameters

Some parameters of the preconditioners are common with the [FGMRES Common Parameters](#). The routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

For the ILU0 preconditioner:

`ipar(2)` - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar(6)` is set to 0, then error messages are not generated at all.

`ipar(6)` - specifies whether error messages are generated. If its value is not equal to 0, the ILU0 routine returns error messages as specified by the parameter `ipar(2)`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter `ierr`. The default value is 1.

For the ILUT preconditioner:

`ipar(2)` - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar(6)` is set to 0, then error messages are not generated at all.

`ipar(6)` - specifies whether error messages are generated. If its value is not equal to 0, the ILUT routine returns error messages as specified by the parameter `ipar(2)`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter `ierr`. The default value is 1.

`ipar(7)` - if its value is greater than 0, the ILUT routine generates warning messages as specified by the parameter `ipar(2)` and continues calculations. If its value is equal to 0, the routine returns a positive value of the parameter `ierr`. If its value is less than 0, the routine generates a warning message as specified by the parameter `ipar(2)` and returns a positive value of the parameter `ierr`. The default value is 1.

dcsrilo0

ILU0 preconditioner based on incomplete LU factorization of a sparse matrix.

Syntax

Fortran:

```
call dcsrilo0(n, a, ia, ja, bilu0, ipar, dpar, ierr)
```

C:

```
dcsrilo0(&n, a, ia, ja, bilu0, ipar, dpar, &ierr);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine `dcsrilo0` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L^* U$, where L is a lower triangular matrix with a unit diagonal, U is an upper triangular matrix with a non-unit diagonal, and the portrait of the original matrix A is used to store the incomplete factors L and U .

Input Parameters

<code>n</code>	INTEGER. Size (number of rows or columns) of the original square n -by- n matrix A .
<code>a</code>	DOUBLE PRECISION. Array containing the set of elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to the <code>values</code> array description in the Sparse Matrix Storage Format for more details.
<code>ia</code>	INTEGER. Array of size $(n+1)$ containing begin indices of rows of the matrix A such that $ia(i)$ is the index in the array A of the first non-zero element from the row i . The value of the last element $ia(n+1)$ is equal to the number of non-zero elements in the matrix A plus one. Refer to the <code>rowIndex</code> array description in the Sparse Matrix Storage Format for more details.
<code>ja</code>	INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its size is equal to the size of the array <code>a</code> . Refer to the <code>columns</code> array description in the Sparse Matrix Storage Format for more details.

NOTE Column indices must be in ascending order for each row of matrix.

<code>ipar</code>	INTEGER array of size 128. This parameter specifies the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the <code>ipar</code> array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.
-------------------	---

ipar(31)

specifies how the routine operates when a zero diagonal element occurs during calculation. If this parameter is set to 0 (the default value set by the routine `dfgmres_init`), then the calculations are stopped and the routine returns a non-zero error value. Otherwise, the diagonal element is set to the value of *dpar*(32) and the calculations continue.

NOTE You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER *ipar*(31) works, there is no guarantee of future compatibility with Intel MKL.

dpar

DOUBLE PRECISION array of size 128. This parameter specifies the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries specific to ILU0 are listed below.

dpar(31)

specifies a small value, which is compared with the computed diagonal elements. When *ipar*(31) is not 0, then diagonal elements less than *dpar*(31) are set to *dpar*(32). The default value is 1.0D-16.

NOTE This parameter can be set to the negative value, because the calculation uses its absolute value.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

dpar(32)

specifies the value that is assigned to the diagonal element if its value is less than *dpar*(31) (see above). The default value is 1.0D-10.

NOTE You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION *ipar*(32) works, there is no guarantee of future compatibility with Intel MKL.

Output Parameters

bilu0

DOUBLE PRECISION. Array *B* containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in direct sparse solvers. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the [Sparse Matrix Storage Format](#) section for more details.

ierr

INTEGER. Error flag, gives information about the routine completion.

NOTE To present the resulting preconditioning matrix in the CSR format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

Return Values

<i>ierr</i> =0	Indicates that the task completed normally.
<i>ierr</i> =-101	Indicates that the routine was interrupted and that error occurred: at least one diagonal element is omitted from the matrix in CSR format (see Sparse Matrix Storage Format).
<i>ierr</i> =-102	Indicates that the routine was interrupted because the matrix contains a diagonal element with the value of zero.
<i>ierr</i> =-103	Indicates that the routine was interrupted because the matrix contains a diagonal element which is so small that it could cause an overflow, or that it would cause a bad approximation to ILU0.
<i>ierr</i> =-104	Indicates that the routine was because the memory is insufficient for the internal work array.
<i>ierr</i> =-105	Indicates that the routine was because the input matrix size <i>n</i> is less than or equal to 0.
<i>ierr</i> =-106	Indicates that the routine was because the column indices <i>ja</i> are not in the ascending order.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilo0 (n, a, ia, ja, bilu0, ipar, dpar, ierr)
INTEGER n, ierr, ipar(128)
INTEGER ia(*), ja(*)
DOUBLE PRECISION a(*), bilu0(*), dpar(128)
```

C:

```
void dcsrilo0 (int *n, double *a, int *ia, int *ja, double *bilu0, int *ipar, double *dpar, int *ierr);
```

dcsrilot

ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.

Syntax

Fortran:

```
call dcsrilot(n, a, ia, ja, bilut, bilut, ibilut, jibilut, tol, maxfil, ipar, dpar,
ierr)
```

C:

```
dcsrilot(&n, a, ia, ja, bilut, bilut, ibilut, jibilut, &tol, &maxfil, ipar, dpar,
&ierr);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine `dcsrilut` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L^* U$, where L is a lower triangular matrix with unit diagonal and U is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors L and U :

- 1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter `tol`, and
- 2) the number of the non-zero elements in each row of the resulting L and U factors must not be greater than the value of the parameter `maxfil`.

Input Parameters

<code>n</code>	INTEGER. Size (number of rows or columns) of the original square n -by- n matrix A .
<code>a</code>	DOUBLE PRECISION. Array containing all non-zero elements of the matrix A . The length of the array is equal to their number. Refer to <code>values</code> array description in the Sparse Matrix Storage Format section for more details.
<code>ia</code>	INTEGER. Array of size $(n+1)$ containing indices of non-zero elements in the array A . $ia(i)$ is the index of the first non-zero element from the row i . The value of the last element $ia(n+1)$ is equal to the number of non-zeros in the matrix A plus one. Refer to the <code>rowIndex</code> array description in the Sparse Matrix Storage Format for more details.
<code>ja</code>	INTEGER. Array of size equal to the size of the array <code>a</code> . This array contains the column numbers for each non-zero element of the matrix A . Refer to the <code>columns</code> array description in the Sparse Matrix Storage Format for more details.

NOTE Column numbers must be in ascending order for each row of matrix.

<code>tol</code>	DOUBLE PRECISION. Tolerance for threshold criterion for the resulting entries of the preconditioner.
<code>maxfil</code>	INTEGER. Maximum fill-in, which is half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner can not exceed $(2 * maxfil + 1)$.
<code>ipar</code>	INTEGER array of size 128. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the <code>ipar</code> array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.
<code>ipar(31)</code>	specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter <code>tol</code> . If <code>ipar(31) = 0</code> , then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to a value determined by <code>dpar(31)</code> (see its description below), and the calculations continue.

NOTE There is no default value for `ipar(31)` even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

NOTE You must declare the array `ipar` with length 128. While defining the array in the code as INTEGER `ipar(31)` works, there is no guarantee of future compatibility with Intel MKL.

`dpar`

DOUBLE PRECISION array of size 128. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the `dpar` array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

`dpar(31)`

used to adjust the value of small diagonal elements. Diagonal elements with a value less than the current matrix row norm multiplied by `tol` are replaced with the value of `dpar(31)` multiplied by the matrix row norm.

NOTE There is no default value for `dpar(31)` entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

NOTE You must declare the array `dpar` with length 128. While defining the array in the code as DOUBLE PRECISION `ipar(31)` works, there is no guarantee of future compatibility with Intel MKL.

Output Parameters

`bilut`

DOUBLE PRECISION. Array containing non-zero elements of the resulting preconditioning matrix B , stored in the format accepted in the direct sparse solvers. Refer to the `values` array description in the [Sparse Matrix Storage Format](#) for more details. The size of the array is equal to $(2*maxfil+1)*n-maxfil*(maxfil+1)+1$.

NOTE Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

`ibilut`

INTEGER. Array of size $(n+1)$ containing indices of non-zero elements in the array `bilut`. `ibilut(i)` is the index of the first non-zero element from the row i . The value of the last element `ibilut(n+1)` is equal to the number of non-zeros in the matrix B plus one. Refer to the `rowIndex` array description in the [Sparse Matrix Storage Format](#) for more details.

<i>jbilut</i>	INTEGER. Array, its size is equal to the size of the array <i>bilut</i> . This array contains the column numbers for each non-zero element of the matrix <i>B</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format for more details.
<i>ierr</i>	INTEGER. Error flag, informs about the routine completion.

Return Values

<i>ierr</i> =0	Indicates that the task completed normally.
<i>ierr</i> =-101	Indicates that the routine was interrupted because of an error: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.
<i>ierr</i> =-102	Indicates that the routine was interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as <i>dpar</i> (31)=0.
<i>ierr</i> =-103	Indicates that the routine was interrupted because the element <i>ia</i> (<i>i</i> +1) is less than or equal to the element <i>ia</i> (<i>i</i>) (see Sparse Matrix Storage Format).
<i>ierr</i> =-104	Indicates that the routine was interrupted because the memory is insufficient for the internal work arrays.
<i>ierr</i> =-105	Indicates that the routine was interrupted because the input value of <i>maxfil</i> is less than 0.
<i>ierr</i> =-106	Indicates that the routine was interrupted because the size <i>n</i> of the input matrix is less than 0.
<i>ierr</i> =-107	Indicates that the routine was interrupted because an element of the array <i>ja</i> is less than 0, or greater than <i>n</i> (see Sparse Matrix Storage Format).
<i>ierr</i> =101	The value of <i>maxfil</i> is greater than or equal to <i>n</i> . The calculation is performed with the value of <i>maxfil</i> set to (<i>n</i> -1).
<i>ierr</i> =102	The value of <i>tol</i> is less than 0. The calculation is performed with the value of the parameter set to (- <i>tol</i>).
<i>ierr</i> =103	The absolute value of <i>tol</i> is greater than value of <i>dpar</i> (31); it can result in instability of the calculation.
<i>ierr</i> =104	The value of <i>dpar</i> (31) is equal to 0. It can cause calculations to fail.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilut (n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
INTEGER n, ierr, ipar(*), maxfil
INTEGER ia(*), ja(*), ibilut(*), jbilut(*)
DOUBLE PRECISION a(*), bilut(*), dpar(*), tol
```

C:

```
void dcsrilut (int *n, double *a, int *ia, int *ja, double *bilut, int *ibilut, int *jbilut, double
*tol, int *maxfil, int *ipar, double *dpar, int *ierr);
```

Calling Sparse Solver and Preconditioner Routines from C/C+

+

All of the Intel MKL sparse solver and preconditioner routines is designed to be called easily from FORTRAN 77 or Fortran 90. However, any of these routines can be invoked directly from C or C++ if you are familiar with the inter-language calling conventions of your platforms. These conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from Fortran to C/C++, and the platform specific method of decoration for Fortran external names.

To promote portability, the C header files provide a set of macros and type definitions intended to hide the inter-language calling conventions and provide an interface to the Intel MKL sparse solver routines that appears natural for C/C++.

For example, consider a hypothetical library routine `foo` that takes a real vector of length `n`, and returns an integer status. Fortran users would access such a function as:

```
INTEGER n, status, foo
REAL x(*)
status = foo(x, n)
```

As noted above, to invoke `foo`, C users need to know what C data types correspond to Fortran types `INTEGER` and `REAL`; what argument passing mechanism the Fortran compiler uses; and what, if any, name decoration the Fortran compiler performs when generating the external symbol `foo`.

However, by using the C specific header file, for example `mkl_solver.h`, the invocation of `foo`, within a C program would look as follows:

```
#include "mkl_solver.h"
_INTEGER_t i, status;
_REAL_t x[];
status = foo( x, i );
```

Note that in the above example, the header file `mkl_solver.h` provides definitions for the types `_INTEGER_t` and `_REAL_t` that correspond to the Fortran types `INTEGER` and `REAL`.

To simplify calling of the Intel MKL sparse solver routines from C and C++, the following approach of providing C definitions of Fortran types is used: if an argument or a result from a sparse solver is documented as having the Fortran language specific type `XXX`, then the C and C++ header files provide an appropriate C language type definitions for the name `_XXX_t`.

Caveat for C Users

One of the key differences between C/C++ and Fortran is the argument passing mechanisms for the languages: Fortran programs pass arguments by reference and C/C++ programs pass arguments by value. In the above example, the header file `mkl_solver.h` attempts to hide this difference by defining a macro `foo`, which takes the address of the appropriate arguments. For example, on the Tru64 UNIX* operating system `mkl_solver.h` defines the macro as follows:

```
#define foo(a,b) foo_((a), &(b))
```

Note how constants are treated when using the macro form of `foo`. `foo(x, 10)` is converted into `foo_(x, &10)`. In a strictly ANSI compliant C compiler, taking the address of a constant is not permitted, so a strictly conforming program would look like:

```
INTEGER_t iTen = 10;
_REAL_t * x;
status = foo( x, iTen );
```

However, some C compilers in a non-ANSI compliant mode enable taking the address of a constant for ease of use with Fortran programs. The form `foo(x, 10)` is acceptable for such compilers.

Vector Mathematical Functions

This chapter describes Intel® MKL Vector Mathematical Functions Library (VML), which computes a mathematical function of each of the vector elements. VML includes a set of highly optimized functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Application programs that improve performance with VML include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VML functions fall into the following groups according to the operations they perform:

- [VML Mathematical Functions](#) compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- [VML Pack/Unpack Functions](#) convert to and from vectors with positive increment indexing, vector indexing, and mask indexing (see [Appendix B](#) for details on vector indexing methods).
- [VML Service Functions](#) set/get the accuracy modes and the error codes, and free memory.

The VML mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VML mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations.

The Intel MKL interfaces are given in the following include files:

- `mkl_vml.f77`, which declares the FORTRAN 77 interfaces
- `mkl_vml.f90`, which declares the Fortran 90 interfaces; the `mkl_vml.fi` include file available in the previous versions of Intel MKL is retained for backward compatibility
- `mkl_vml_functions.h`, which declares the C interfaces

The following directories provide examples that demonstrate how to use the VML functions:

`$(MKL)/examples/vmlc/source`

`$(MKL)/examples/vmlf/source`

See VML performance and accuracy data in the online VML Performance and Accuracy Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Data Types, Accuracy Modes, and Performance Tips

VML includes mathematical and pack/unpack vector functions for single and double precision vector arguments of real and complex types. The library provides Fortran- and C-interfaces for all functions, including the associated service functions. The Function Naming Conventions section below shows how to call these functions from different languages.

Performance depends on a number of factors, including vectorization and threading overhead. The recommended usage is as follows:

- Use VML for vector lengths larger than 40 elements.

- Use the Intel® Compiler for vector lengths less than 40 elements.

All VML vector functions support the following accuracy modes:

- High Accuracy (HA), the default mode
- Low Accuracy (LA), which improves performance by reducing accuracy of the two least significant bits
- Enhanced Performance (EP), which provides better performance at the cost of significantly reduced accuracy. Approximately half of the bits in the mantissa are correct.

Note that using the EP mode does not guarantee accurate processing of corner cases and special values. Although the default accuracy is HA, LA is sufficient in most cases. For applications that require less accuracy (for example, media applications, some Monte Carlo simulations, etc.), the EP mode may be sufficient.

VML handles special values in accordance with the C99 standard [C99].

Use the `vmlSetMode(mode)` function (see [Table "Values of the mode Parameter"](#)) to switch between the HA, LA, and EP modes. The `vmlGetMode()` function returns the current mode.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

[Function Naming Conventions](#)

Function Naming Conventions

The VML function names are lowercase for Fortran (`vsabs`) and of mixed (lower and upper) case for C (`vsAbs`).

The VML mathematical and pack/unpack function names have the following structure:

`v[m]<?><name><mod>`

where

- `v` is a prefix indicating vector operations.
- `[m]` is an optional prefix for mathematical functions that indicates additional argument to specify a VML mode for a given function call (see `vmlSetMode` for possible values and their description).
- `<?>` is a precision prefix that indicates one of the following the data types:

<code>s</code>	REAL for the Fortran interface, or <code>float</code> for the C interface
<code>d</code>	DOUBLE PRECISION for the Fortran interface, or <code>double</code> for the C interface.
<code>c</code>	COMPLEX for the Fortran interface, or <code>MKL_Complex8</code> for the C interface.
<code>z</code>	DOUBLE COMPLEX for the Fortran interface, or <code>MKL_Complex16</code> for the C interface.

- `<name>` indicates the function short name, with some of its letters in uppercase for the C interface. See examples in [Table "VML Mathematical Functions"](#).
- `<mod>` field (written in uppercase for the C interface) is present only in the pack/unpack functions and indicates the indexing method used:

<code>i</code>	indexing with a positive increment
<code>v</code>	indexing with an index vector
<code>m</code>	indexing with a mask vector.

The VML service function names have the following structure:

`vml<name>`

where

`<name>` indicates the function short name, with some of its letters in uppercase for the C interface. See examples in [Table "VML Service Functions"](#).

To call VML functions from an application program, use conventional function calls. For example, call the vector single precision real exponential function as

`call vsexp (n, a, y)` for the Fortran interface, or

`call vmsexp (n, a, y, mode)` for the Fortran interface with a specified mode, or

`vsExp (n, a, y);` for the C interface.

Function Interfaces

VML interfaces include the function names and argument lists. The following sections describe the Fortran and C interfaces for the VML functions. Note that some of the functions have multiple input and output arguments

Some VML functions may also take scalar arguments as input. See the function description for the naming conventions of such arguments.

VML Mathematical Functions

Fortran:

```
call v<?><name>( n, a, [scalar input arguments,] y )
call v<?><name>( n, a, b, [scalar input arguments,] y )
call v<?><name>( n, a, y, z )
call vm<?><name>( n, a, [scalar input arguments,] y, mode )
call vm<?><name>( n, a, b, [scalar input arguments,] y, mode )
call vm<?><name>( n, a, y, z, mode )
```

C:

```
v<?><name>( n, a, [scalar input arguments,] y );
v<?><name>( n, a, b, [scalar input arguments,] y );
v<?><name>( n, a, y, z );
vm<?><name>( n, a, [scalar input arguments,] y, mode );
vm<?><name>( n, a, b, [scalar input arguments,] y, mode );
vm<?><name>( n, a, y, z, mode );
```

Pack Functions

Fortran:

```
call v<?>packi( n, a, inca, y )
call v<?>packv( n, a, ia, y )
call v<?>packm( n, a, ma, y )
```

C:

```
v<?>PackI( n, a, inca, y );
v<?>PackV( n, a, ia, y );
v<?>PackM( n, a, ma, y );
```

Unpack Functions

Fortran:

```
call v<?>unpacki( n, a, y, incy )
call v<?>unpackv( n, a, y, iy )
call v<?>unpackm( n, a, y, my )
```

C:

```
v<?>UnpackI( n, a, y, incy );
v<?>UnpackV( n, a, y, iy );
v<?>UnpackM( n, a, y, my );
```

Service Functions

Fortran:

```
oldmode = vmlsetmode( mode )
mode = vmlgetmode( )
olderr = vmlseterrstatus( err )
err = vmlgeterrstatus( )
olderr = vmlclearerrstatus( )
oldcallback = vmlseterrorcallback( callback )
callback = vmlgeterrorcallback( )
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldmode = vmlSetMode( mode );
mode = vmlGetMode( void );
olderr = vmlSetErrStatus( err );
err = vmlGetErrStatus( void );
olderr = vmlClearErrStatus( void );
oldcallback = vmlsetErrorCallBack( callback );
callback = vmlgetErrorCallBack( void );
oldcallback = vmlClearErrorCallBack( void );
```

Note that `oldmode`, `olderr`, and `oldcallback` refer to settings prior to the call.

Input Parameters

<i>n</i>	number of elements to be calculated
<i>a</i>	first input vector
<i>b</i>	second input vector
<i>inca</i>	vector increment for the input vector <i>a</i>
<i>ia</i>	index vector for the input vector <i>a</i>
<i>ma</i>	mask vector for the input vector <i>a</i>
<i>incy</i>	vector increment for the output vector <i>y</i>
<i>iy</i>	index vector for the output vector <i>y</i>
<i>my</i>	mask vector for the output vector <i>y</i>
<i>err</i>	error code
<i>mode</i>	VML mode
<i>callback</i>	address of the callback function

Output Parameters

<i>y</i>	first output vector
<i>z</i>	second output vector
<i>err</i>	error code
<i>mode</i>	VML mode
<i>olderr</i>	former error code
<i>oldmode</i>	former VML mode
<i>callback</i>	address of the callback function
<i>oldcallback</i>	address of the former callback function

See the data types of the parameters used in each function in the respective function description section. All the Intel MKL VML mathematical functions can perform in-place operations.

Vector Indexing Methods

VML mathematical functions work only with unit stride. To accommodate arrays with other increments, or more complicated indexing, you can gather the elements into a contiguous vector and then scatter them after the computation is complete.

VML uses the three following indexing methods to do this task:

- positive increment
- index vector
- mask vector

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the *<mod>* field in [Function Naming Conventions](#)). For more information on the indexing methods, see [Vector Arguments in VML](#) in Appendix B.

Error Diagnostics

The VML mathematical functions incorporate the error handling mechanism, which is controlled by the following service functions:

<code>vmlGetErrStatus,</code> <code>vmlSetErrStatus,</code> <code>vmlClearErrStatus</code>	These functions operate with a global variable called VML Error Status. The VML Error Status flags an error, a warning, or a successful execution of a VML function.
<code>vmlGetErrCallBack,</code> <code>vmlSetErrCallBack,</code> <code>vmlClearErrCallBack</code>	These functions enable you to customize the error handling. For example, you can identify a particular argument in a vector where an error occurred or that caused a warning.
<code>vmlSetMode, vmlGetMode</code>	These functions get and set a VML mode. If you set a new VML mode using the <code>vmlSetMode</code> function, you can store the previous VML mode returned by the routine and restore it at any point of your application.

If both an error and a warning situation occur during the function call, the VML Error Status variable keeps only the value of the error code. See [Table "Values of the VML Error Status"](#) for possible values. If a VML function does not encounter errors or warnings, it sets the VML Error Status to `VML_STATUS_OK`.

If you use the Fortran interface, call the error reporting function `XERBLA` to receive information about correctness of input arguments (`VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM`). See [Table "Values of the VML Error Status"](#) for details.

You can use the `vmlSetMode` and `vmlGetMode` functions to modify error handling behavior. Depending on the VML mode, the error handling behavior includes the following operations:

- setting the VML Error Status to a value corresponding to the observed error or warning
- setting the `errno` variable to one of the values described in [Table "Set Values of the `errno` Variable"](#)
- writing error text information to the `stderr` stream
- raising the appropriate exception on an error, if necessary
- calling the additional error handler callback function that is set by `vmlSetErrorHandler`.

[Set Values of the `errno` Variable](#)

Value of <code>errno</code>	Description
<code>0</code>	No errors are detected.
<code>EINVAL</code>	The array dimension is not positive.
<code>EACCES</code>	NULL pointer is passed.
<code>EDOM</code>	At least one of array values is out of a range of definition.
<code>ERANGE</code>	At least one of array values caused a singularity, overflow or underflow.

VML Mathematical Functions

This section describes VML functions that compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data both for Fortran- and C-interfaces, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- `FLT_MAX` denotes the maximum number representable in single precision real data type
- `DBL_MAX` denotes the maximum number representable in double precision real data type

[Table "VML Mathematical Functions"](#) lists available mathematical functions and associated data types.

VML Mathematical Functions

Function	Data Types	Description
Arithmetic Functions		
<code>v?Add</code>	<code>s, d, c, z</code>	Addition of vector elements
<code>v?Sub</code>	<code>s, d, c, z</code>	Subtraction of vector elements
<code>v?Sqr</code>	<code>s, d</code>	Squaring of vector elements
<code>v?Mul</code>	<code>s, d, c, z</code>	Multiplication of vector elements
<code>v?MulByConj</code>	<code>c, z</code>	Multiplication of elements of one vector by conjugated elements of the second vector
<code>v?Conj</code>	<code>c, z</code>	Conjugation of vector elements
<code>v?Abs</code>	<code>s, d, c, z</code>	Computation of the absolute value of vector elements
<code>v?Arg</code>	<code>c, z</code>	Computation of the argument of vector elements
<code>v?LinearFrac</code>	<code>s, d</code>	Linear fraction transformation of vectors
Power and Root Functions		
<code>v?Inv</code>	<code>s, d</code>	Inversion of vector elements

Function	Data Types	Description
v?Div	s, d, c, z	Division of elements of one vector by elements of the second vector
v?Sqrt	s, d, c, z	Computation of the square root of vector elements
v?InvSqrt	s, d	Computation of the inverse square root of vector elements
v?Cbrt	s, d	Computation of the cube root of vector elements
v?InvCbrt	s, d	Computation of the inverse cube root of vector elements
v?Pow2o3	s, d	Raising each vector element to the power of 2/3
v?Pow3o2	s, d	Raising each vector element to the power of 3/2
v?Pow	s, d, c, z	Raising each vector element to the specified power
v?Powx	s, d, c, z	Raising each vector element to the constant power
v?Hypot	s, d	Computation of the square root of sum of squares
Exponential and Logarithmic Functions		
v?Exp	s, d, c, z	Computation of the exponential of vector elements
v?Expm1	s, d	Computation of the exponential of vector elements decreased by 1
v?Ln	s, d, c, z	Computation of the natural logarithm of vector elements
v?Log10	s, d, c, z	Computation of the denary logarithm of vector elements
v?Log1p	s, d	Computation of the natural logarithm of vector elements that are increased by 1
Trigonometric Functions		
v?Cos	s, d, c, z	Computation of the cosine of vector elements
v?Sin	s, d, c, z	Computation of the sine of vector elements
v?SinCos	s, d	Computation of the sine and cosine of vector elements
v?CIS	c, z	Computation of the complex exponent of vector elements (cosine and sine combined to complex value)
v?Tan	s, d, c, z	Computation of the tangent of vector elements
v?Acos	s, d, c, z	Computation of the inverse cosine of vector elements
v?Asin	s, d, c, z	Computation of the inverse sine of vector elements
v?Atan	s, d, c, z	Computation of the inverse tangent of vector elements
v?Atan2	s, d	Computation of the four-quadrant inverse tangent of elements of two vectors
Hyperbolic Functions		
v?Cosh	s, d, c, z	Computation of the hyperbolic cosine of vector elements
v?Sinh	s, d, c, z	Computation of the hyperbolic sine of vector elements
v?Tanh	s, d, c, z	Computation of the hyperbolic tangent of vector elements
v?Acosh	s, d, c, z	Computation of the inverse hyperbolic cosine of vector elements
v?Asinh	s, d, c, z	Computation of the inverse hyperbolic sine of vector elements
v?Atanh	s, d, c, z	Computation of the inverse hyperbolic tangent of vector elements.
Special Functions		
v?Erf	s, d	Computation of the error function value of vector elements
v?Erfc	s, d	Computation of the complementary error function value of vector elements
v?CdfNorm	s, d	Computation of the cumulative normal distribution function value of vector elements
v?ErfInv	s, d	Computation of the inverse error function value of vector elements
v?ErfcInv	s, d	Computation of the inverse complementary error function value of vector elements
v?CdfNormInv	s, d	Computation of the inverse cumulative normal distribution function value of vector elements
v?LGamma	s, d	Computation of the natural logarithm for the absolute value of the gamma function of vector elements
v?TGamma	s, d	Computation of the gamma function of vector elements
Rounding Functions		
v?Floor	s, d	Rounding towards minus infinity
v?Ceil	s, d	Rounding towards plus infinity
v?Trunc	s, d	Rounding towards zero infinity

Function	Data Types	Description
v?Round	s, d	Rounding to nearest integer
v?NearbyInt	s, d	Rounding according to current mode
v?Rint	s, d	Rounding according to current mode and raising inexact result exception
v?Modf	s, d	Computation of the integer and fraction parts

Special Value Notations

This section defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- z, z_1, z_2 , etc. denote complex numbers.
- $i, i^2=-1$ is the imaginary unit.
- x, X, x_1, x_2 , etc. denote real imaginary parts.
- y, Y, y_1, y_2 , etc. denote imaginary parts.
- X and Y represent any finite positive IEEE-754 floating point values, if not stated otherwise.
- Quiet NaN and signaling NaN are denoted with QNAN and SNAN, respectively.
- The IEEE-754 positive infinities or floating-point numbers are denoted with a + sign before X, Y , etc.
- The IEEE-754 negative infinities or floating-point numbers are denoted with a - sign before X, Y , etc.

$\text{CONJ}(z)$ and $\text{CIS}(z)$ are defined as follows:

$$\text{CONJ}(x+i\cdot y)=x-i\cdot y$$

$$\text{CIS}(y)=\cos(y)+i\cdot \sin(y).$$

The special value tables show the result of the function for the z argument at the intersection of the $\text{RE}(z)$ column and the $i*\text{IM}(z)$ row. If the function raises an exception on the argument z , the lower part of this cell shows the raised exception and the VML Error Status. An empty cell indicates that this argument is normal and the result is defined mathematically.

Arithmetic Functions

Arithmetic functions perform the basic mathematical operations like addition, subtraction, multiplication or computation of the absolute value of the vector elements.

v?Add

Performs element by element addition of vector a and vector b .

Syntax

Fortran:

```
call vsadd( n, a, b, y )
call vmsadd( n, a, b, y, mode )
call vdadd( n, a, b, y )
call vmdadd( n, a, b, y, mode )
call vcadd( n, a, b, y )
call vmcadd( n, a, b, y, mode )
call vzadd( n, a, b, y )
call vmzadd( n, a, b, y, mode )
```

C:

```
vsAdd( n, a, b, y );
vmsAdd( n, a, b, y, mode );
vdAdd( n, a, b, y );
vmdAdd( n, a, b, y, mode );
vcAdd( n, a, b, y );
vmcAdd( n, a, b, y, mode );
vzAdd( n, a, b, y );
vmzAdd( n, a, b, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vsadd, vmsadd DOUBLE PRECISION for vdadd, vmdadd COMPLEX for vcadd, vmcadd DOUBLE COMPLEX for vzadd, vmzadd Fortran 90: REAL, INTENT(IN) for vsadd, vmsadd DOUBLE PRECISION, INTENT(IN) for vdadd, vmdadd COMPLEX, INTENT(IN) for vcadd, vmcadd DOUBLE COMPLEX, INTENT(IN) for vzadd, vmzadd C: const float* for vsAdd, vmsAdd const double* for vdAdd, vmdAdd const MKL_Complex8* for vcAdd, vmcAdd const MKL_Complex16* for vzAdd, vmzAdd	FORTRAN: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsadd, vmsadd DOUBLE PRECISION for vdadd, vmdadd COMPLEX, for vcadd, vmcadd DOUBLE COMPLEX for vzadd, vmzadd Fortran 90: REAL, INTENT (OUT) for vsadd, vmsadd DOUBLE PRECISION, INTENT (OUT) for vdadd, vmdadd COMPLEX, INTENT (OUT) for vcadd, vmcadd DOUBLE COMPLEX, INTENT (OUT) for vzadd, vmzadd C: float* for vsAdd, vmsadd double* for vdAdd, vmdadd MKL_Complex8* for vcAdd, vmcadd MKL_Complex16* for vzAdd, vmzadd	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Add` function performs element by element addition of vector *a* and vector *b*.

Special values for Real Function `v?Add(x)`

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	+0	
-0	-0	-0	
+∞	+∞	+∞	
+∞	-∞	QNAN	INVALID
-∞	+∞	QNAN	INVALID
-∞	-∞	-∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID

Argument 1	Argument 2	Result	Exception
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Add}(x_1+i*y_1, x_2+i*y_2) = (x_1+x_2) + i*(y_1+y_2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Sub

Performs element by element subtraction of vector *b* from vector *a*.

Syntax

Fortran:

```
call vssub( n, a, b, y )
call vmssub( n, a, b, y, mode )
call vdsub( n, a, b, y )
call vmdsub( n, a, b, y, mode )
call vcsub( n, a, b, y )
call vmcsub( n, a, b, y, mode )
call vzsub( n, a, b, y )
call vmzsub( n, a, b, y, mode )
```

C:

```
vsSub( n, a, b, y );
vmsSub( n, a, b, y, mode );
vdSub( n, a, b, y );
vmdSub( n, a, b, y, mode );
vcSub( n, a, b, y );
vmcSub( n, a, b, y, mode );
vzSub( n, a, b, y );
vmzSub( n, a, b, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vssub, vmssub DOUBLE PRECISION for vdsub, vmdsub COMPLEX for vcsub, vmcsu DOUBLE COMPLEX for vzsub, vmzsub Fortran 90: REAL, INTENT (IN) for vssub, vmssub DOUBLE PRECISION, INTENT (IN) for vdsub, vmdsub COMPLEX, INTENT (IN) for vcsub, vmcsu DOUBLE COMPLEX, INTENT (IN) for vzsub, vmzsub C: const float* for vsSub, vmssub const double* for vdSub, vmdsub const MKL_Complex8* for vcSub, vmcsu const MKL_Complex16* for vzSub, vmzsub	FORTRAN: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vssub, vmssub DOUBLE PRECISION for vdsub, vmdsub COMPLEX for vcsub, vmcsu DOUBLE COMPLEX for vzsub, vmzsub Fortran 90: REALINTENT (OUT) for vssub, vmssub	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT (OUT) for vdsub, vmdsub	
	COMPLEX, INTENT (OUT) for vcsub, vmcsub	
	DOUBLE COMPLEX, INTENT (OUT) for vzsub, vmzsub	
C:	float* for vsSub, vmssub	
	double* for vdSub, vmdsub	
	MKL_Complex8* for vcSub, vmcsub	
	MKL_Complex16* for vzSub, vmzsub	

Description

The v?Sub function performs element by element subtraction of vector b from vector a .

Special values for Real Function v?Sub(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	-0	
-0	-0	+0	
+∞	+∞	QNAN	INVALID
+∞	-∞	+∞	
-∞	+∞	-∞	
-∞	-∞	QNAN	INVALID
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Sub}(x_1 + i \cdot y_1, x_2 + i \cdot y_2) = (x_1 - x_2) + i \cdot (y_1 - y_2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Sqr

Performs element by element squaring of the vector.

Syntax

Fortran:

```
call vssqr( n, a, y )
call vmssqr( n, a, y, mode )
call vdsqr( n, a, y )
```

```
call vmdsqr( n, a, y, mode )
```

C:

```
vsSqr( n, a, y );
vmsSqr( n, a, y, mode );
vdSqr( n, a, y );
vmdSqr( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vssqr, vmssqr DOUBLE PRECISION for vdsqr, vmdsqr Fortran 90: REAL, INTENT(IN) for vssqr, vmssqr DOUBLE PRECISION, INTENT(IN) for vdsqr, vmdsqr C: const float* for vsSqr, vmssqr const double* for vdSqr, vmdsqr	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vssqr, vmssqr DOUBLE PRECISION for vdsqr, vmdsqr	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT(OUT) for vssqr, vmssqr	
	DOUBLE PRECISION, INTENT(OUT) for vdsqr, vmdsqr	
	C: float* for vsSqr, vmssqr double* for vdSqr, vmdsqr	

Description

The v?Sqr function performs element by element squaring of the vector.

Special Values for Real Function v?Sqr(x)

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?Mul

Performs element by element multiplication of vector *a* and vector *b*.

Syntax

Fortran:

```
call vsmul( n, a, b, y )
call vmsmul( n, a, b, y, mode )
call vdmul( n, a, b, y )
call vmdmul( n, a, b, y, mode )
call vcmul( n, a, b, y )
call vmcmul( n, a, b, y, mode )
call vzmul( n, a, b, y )
call vmzcmul( n, a, b, y, mode )
```

C:

```
vsMul( n, a, b, y );
vmsMul( n, a, b, y, mode );
vdMul( n, a, b, y );
vmdMul( n, a, b, y, mode );
vcMul( n, a, b, y );
vmcMul( n, a, b, y, mode );
vzMul( n, a, b, y );
```

```
vmzMul( n, a, b, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vsmul, vmsmul DOUBLE PRECISION for vdmul, vmdmul COMPLEX for vcmul, vmcmul DOUBLE COMPLEX for vzmul, vmzmul Fortran 90: REAL, INTENT (IN) for vsmul, vmsmul DOUBLE PRECISION, INTENT (IN) for vdmul, vmdmul COMPLEX, INTENT (IN) for vcmul, vmcmul DOUBLE COMPLEX, INTENT (IN) for vzmul, vmzmul C: const float* for vsMul, vmsmul const double* for vdMul, vmdmul const MKL_Complex8* for vcMul, vmcMul const MKL_Complex16* for vzMul, vmzMul	FORTRAN: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsmul, vmsmul	FORTRAN: Array that specifies the output vector <i>y</i> .

Name	Type	Description
	DOUBLE PRECISION for vdmul, vmdmul	C: Pointer to an array that contains the output vector y .
	COMPLEX, for vcmul, vmcmul	
	DOUBLE COMPLEX for vzmul, vmzmul	
Fortran 90:	REAL, INTENT (OUT) for vsmul, vmsmul	
	DOUBLE PRECISION, INTENT (OUT) for vdmul, vmdmul

	double* for vdMul, vmdmul	
	MKL_Complex8* for vcMul, vmcMul	
	MKL_Complex16* for vzMul, vmzMul	

Description

The `v?Mul` function performs element by element multiplication of vector a and vector b .

Special values for Real Function `v?Mul(x)`

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	-0	
-0	+0	-0	
-0	-0	+0	
+0	+∞	QNAN	INVALID
+0	-∞	QNAN	INVALID
-0	+∞	QNAN	INVALID
-0	-∞	QNAN	INVALID
+∞	+0	QNAN	INVALID
+∞	-0	QNAN	INVALID
-∞	+0	QNAN	INVALID
-∞	-0	QNAN	INVALID
+∞	+∞	+∞	
+∞	-∞	-∞	
-∞	+∞	-∞	
-∞	-∞	+∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	

Argument 1	Argument 2	Result	Exception
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Mul}(x_1+i*y_1, x_2+i*y_2) = (x_1*x_2 - y_1*y_2) + i*(x_1*y_2 + y_1*x_2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?MulByConj

Performs element by element multiplication of vector a element and conjugated vector b element.

Syntax

Fortran:

```
call vcmulbyconj( n, a, b, y )
call vmcmulbyconj( n, a, b, y, mode )
call vzmulbyconj( n, a, b, y )
call vmzmulbyconj( n, a, b, y, mode )
```

C:

```
vcMulByConj( n, a, b, y );
vmcMulByConj( n, a, b, y, mode );
vzMulByConj( n, a, b, y );
vmzMulByConj( n, a, b, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: COMPLEX for vcmulbyconj, vmcmulbyconj DOUBLE COMPLEX for vzmulbyconj, vmzmulbyconj Fortran 90: COMPLEX, INTENT(IN) for vcmulbyconj, vmcmulbyconj	FORTRAN: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Name	Type	Description
	DOUBLE COMPLEX, INTENT(IN) for vzmulbyconj, vmzmulbyconj C: const MKL_Complex8* for vcMulByConj, vmcMulByConj const MKL_Complex16* for vzMulByConj, vmzMulByConj	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vm1SetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: COMPLEX for vcmulbyconj, vmcmulbyconj DOUBLE COMPLEX for vzmulbyconj, vmzmulbyconj Fortran 90: COMPLEX, INTENT(OUT) for vcmulbyconj, vmcmulbyconj DOUBLE COMPLEX, INTENT(OUT) for vzmulbyconj, vmzmulbyconj C: MKL_Complex8* for vcMulByConj, vmcMulByConj MKL_Complex16* for vzMulByConj, vmzMulByConj	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?MulByConj` function performs element by element multiplication of vector *a* element and conjugated vector *b* element.

Specifications for special values of the functions are found according to the formula

$$\text{MulByConj}(x_1+i*y_1, x_2+i*y_2) = \text{Mul}(x_1+i*y_1, x_2-i*y_2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Conj

Performs element by element conjugation of the vector.

Syntax

Fortran:

```
call vcconj( n, a, y )
call vmcconj( n, a, y, mode )
call vzconj( n, a, y )
call vmzconj( n, a, y, mode )
```

C:

```
vcConj( n, a, y );
vmcConj( n, a, y, mode );
vzConj( n, a, y );
vmzConj( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: COMPLEX, INTENT(IN) for vcconj, vmcconj DOUBLE COMPLEX, INTENT(IN) for vzconj, vmzconj Fortran 90: COMPLEX, INTENT(IN) for vcconj, vmcconj DOUBLE COMPLEX, INTENT(IN) for vzconj, vmzconj C: const MKL_Complex8* for vcConj, vmcConj const MKL_Complex16* for vzConj, vmzConj	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: COMPLEX, for <code>vcconj</code> , <code>vmcconj</code> DOUBLE COMPLEX for <code>vzconj</code> , <code>vmzconj</code> Fortran 90: COMPLEX, INTENT(OUT) for <code>vcconj</code> , <code>vmcconj</code> DOUBLE COMPLEX, INTENT(OUT) for <code>vzconj</code> , <code>vmzconj</code> C: MKL_Complex8* for <code>vcConj</code> , <code>vmcconj</code> MKL_Complex16* for <code>vzConj</code> , <code>vmzconj</code>	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Conj` function performs element by element conjugation of the vector.

No special values are specified. The function does not raise floating-point exceptions.

v?Abs

Computes absolute value of vector elements.

Syntax

Fortran:

```
call vsabs( n, a, y )
call vmsabs( n, a, y, mode )
call vdabs( n, a, y )
call vmdabs( n, a, y, mode )
call vcabs( n, a, y )
call vmcabs( n, a, y, mode )
call vzabs( n, a, y )
call vmzabs( n, a, y, mode )
```

C:

```
vsAbs( n, a, y );
vmsAbs( n, a, y, mode );
vdAbs( n, a, y );
vmdAbs( n, a, y, mode );
vcAbs( n, a, y );
vmcAbs( n, a, y, mode );
vzAbs( n, a, y );
```

```
vmzAbs( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsabs, vmsabs DOUBLE PRECISION for vdabs, vmdabs COMPLEX for vcabs, vmcabs DOUBLE COMPLEX for vzabs, vmzabs Fortran 90: REAL, INTENT (IN) for vsabs, vmsabs DOUBLE PRECISION, INTENT (IN) for vdabs, vmdabs COMPLEX, INTENT (IN) for vcabs, vmcabs DOUBLE COMPLEX, INTENT (IN) for vzabs, vmzabs C: const float* for vsabs, vmsabs const double* for vdabs, vmdabs const MKL_Complex8* for vcAbs, vmcAbs const MKL_Complex16* for vzAbs, vmzAbs	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsabs, vmsabs, vcabs, vmcabs	FORTRAN: Array that specifies the output vector <i>y</i> .

Name	Type	Description
	DOUBLE PRECISION for vdabs, vmdabs, vzabs, vmzabs	C: Pointer to an array that contains the output vector y .
	Fortran 90: REAL, INTENT(OUT) for vsabs, vmsabs, vcabs, vmcabs	
	DOUBLE PRECISION, INTENT(OUT) for vdabs, vmdabs, vzabs, vmzabs	
	C: float* for vsabs, vmsabs, vcAbs, vmcAbs	
	double* for vdabs, vmdabs, vzAbs, vmzAbs	

Description

The $v?Abs$ function computes an absolute value of vector elements.

Special Values for Real Function $v?Abs(x)$

Argument	Result	Exception
+0	+0	
-0	+0	
$+\infty$	$+\infty$	
$-\infty$	$+\infty$	
QNAN	QNAN	
SNAN	QNAN	INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Abs}(z) = \text{Hypot}(\text{RE}(z), \text{IM}(z)).$$

v?Arg

Computes argument of vector elements.

Syntax

Fortran:

```
call vcarg( n, a, y )
call vmcarg( n, a, y, mode )
call vzarg( n, a, y )
call vmzarg( n, a, y, mode )
```

C:

```
vcArg( n, a, y );
vmcArg( n, a, y, mode );
vzArg( n, a, y );
vmzArg( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi

- Fortran 90: `mkl_vml.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN77: COMPLEX for <code>vcarg</code> , <code>vmcarg</code> DOUBLE COMPLEX for <code>vzarg</code> , <code>vmzarg</code> Fortran 90: COMPLEX, INTENT(IN) for <code>vcarg</code> , <code>vmcarg</code> DOUBLE COMPLEX, INTENT(IN) for <code>vzarg</code> , <code>vmzarg</code> C: const <code>MKL_Complex8*</code> for <code>vcArg</code> , <code>vmcArg</code> const <code>MKL_Complex16*</code> for <code>vzArg</code> , <code>vmcArg</code>	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const <code>MKL_INT64</code>	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for <code>vcarg</code> , <code>vmcarg</code> DOUBLE PRECISION for <code>vzarg</code> , <code>vmzarg</code> Fortran 90: REAL, INTENT(OUT) for <code>vcarg</code> , <code>vmcarg</code> DOUBLE PRECISION, INTENT(OUT) for <code>vzarg</code> , <code>vmzarg</code> C: float* for <code>vcArg</code> , <code>vmcArg</code> double* for <code>vzArg</code> , <code>vmcArg</code>	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Arg` function computes argument of vector elements.

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Arg(z)

RE(z)	-∞	-X	-0	+0	+X	+∞	NAN
i·IM(z)							
$+i\cdot\infty$	$+3\cdot\pi/4$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/4$	NAN
$+i\cdot Y$	$+\pi$		$+\pi/2$	$+\pi/2$		$+0$	NAN
$+i\cdot 0$	$+\pi$	$+\pi$	$+\pi$	$+0$	$+0$	$+0$	NAN
$-i\cdot 0$	$-\pi$	$-\pi$	$-\pi$	-0	-0	-0	NAN
$-i\cdot Y$	$-\pi$		$-\pi/2$	$-\pi/2$		-0	NAN
$-i\cdot\infty$	$-3\cdot\pi/4$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/4$	NAN
$+i\cdot N$ N	NAN	NAN	NAN	NAN	NAN	NAN	NAN

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- $\text{Arg}(z) = \text{Atan2}(\text{IM}(z), \text{RE}(z))$.

v?LinearFrac

Performs linear fraction transformation of vectors a and b with scalar parameters.

Syntax**Fortran:**

```
call vslinearfraction( n, a, b, scalea, shifta, scaleb, shiftb, y )
call vmslinearfraction( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
call vdlinearfraction( n, a, b, scalea, shifta, scaleb, shiftb, y )
call vmdlinearfraction( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
```

C:

```
vsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y );
vmsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
vdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
vmdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
```

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for <code>vslinearfrac</code> Fortran 90: REAL, INTENT(OUT) for <code>vslinearfrac</code> DOUBLE PRECISION, INTENT(OUT) for <code>vdlinearfrac</code> C: float* for <code>vsLinearFrac</code> double* for <code>vdLinearFrac</code>	FORTRAN: Array that specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

The `v?LinearFrac` function performs linear fraction transformation of vectors a by vector b with scalar parameters: scaling multipliers $scalea$, $scaleb$ and shifting addends $shifta$, $shiftb$:

$$y[i] = (scalea \cdot a[i] + shifta) / (scaleb \cdot b[i] + shiftb), i=1,2 \dots n$$

The `v?LinearFrac` function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

Threshold Limitations on Input Parameters

$$2^{E_{\text{MIN}}/2} \leq |scalea| \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$2^{E_{\text{MIN}}/2} \leq |scaleb| \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$|shifta| \leq 2^{E_{\text{MAX}}-2}$$

$$|shiftb| \leq 2^{E_{\text{MAX}}-2}$$

$$2^{E_{\text{MIN}}/2} \leq a[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$2^{E_{\text{MIN}}/2} \leq b[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$a[i] \neq - (shifta/scalea) * (1-\delta_1), |\delta_1| \leq 2^{1-(p-1)/2}$$

$$b[i] \neq - (shiftb/scaleb) * (1-\delta_2), |\delta_2| \leq 2^{1-(p-1)/2}$$

E_{MIN} and E_{MAX} are the maximum and minimum exponents and p is the number of significant bits (precision) for corresponding data type according to the ANSI/IEEE Std 754-2008 standard ([[IEEE754](#)]):

- for single precision $E_{\text{MIN}} = -126$, $E_{\text{MAX}} = 127$, $p = 24$
- for double precision $E_{\text{MIN}} = -1022$, $E_{\text{MAX}} = 1023$, $p = 53$

The thresholds become less strict for common cases with $scalea=0$ and/or $scaleb=0$:

- if $scalea=0$, there are no limitations for the values of $a[i]$ and $shifta$
- if $scaleb=0$, there are no limitations for the values of $b[i]$ and $shiftb$

Power and Root Functions

v?Inv

Performs element by element inversion of the vector.

Syntax**Fortran:**

```
call vsinv( n, a, y )
call vmsinv( n, a, y, mode )
call vdinv( n, a, y )
call vmdinv( n, a, y, mode )
```

C:

```
vsInv( n, a, y );
vmsInv( n, a, y, mode );
vdInv( n, a, y );
vmdInv( n, a, y, mode );
```

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsinv, vmsinv DOUBLE PRECISION for vdinv, vmdinv Fortran 90: REAL, INTENT(IN) for vsinv, vmsinv DOUBLE PRECISION, INTENT(IN) for vdinv, vmdinv C: const float* for vsInv, vmsInv const double* for vdInv, vmdInv	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN)	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Name	Type	Description
	C: const MKL_INT64	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsinv, vmsinv DOUBLE PRECISION for vdinv, vmdinv Fortran 90: REAL, INTENT(OUT) for vsinv, vmsinv DOUBLE PRECISION, INTENT(OUT) for vdinv, vmdinv C: float* for vsInv, vmsInv double* for vdInv, vmdInv	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The *v?Inv* function performs element by element inversion of the vector.

Special Values for Real Function *v?Inv(x)*

Argument	Result	VML Error Status	Exception
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
+∞	+0		
-∞	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Div

Performs element by element division of vector *a* by vector *b*

Syntax

Fortran:

```
call vsdiv( n, a, b, y )
call vmsdiv( n, a, b, y, mode )
call vddiv( n, a, b, y )
call vmddiv( n, a, b, y, mode )
call vcdiv( n, a, b, y )
call vmcdiv( n, a, b, y, mode )
call vzdiv( n, a, b, y )
call vmzdiv( n, a, b, y, mode )
```

C:

```
vsDiv( n, a, b, y );
vmsDiv( n, a, b, y, mode );
vdDiv( n, a, b, y );
vmdDiv( n, a, b, y, mode );
vcDiv( n, a, b, y );
vmcDiv( n, a, b, y, mode );
vzDiv( n, a, b, y );
vmzDiv( n, a, b, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vsdiv, vmsdiv DOUBLE PRECISION for vddiv, vmddiv COMPLEX for vcdiv, vmcdiv DOUBLE COMPLEX for vzdiv, vmzdiv Fortran 90: REAL, INTENT(IN) for vsdiv, vmsdiv DOUBLE PRECISION, INTENT(IN) for vddiv, vmddiv COMPLEX, INTENT(IN) for vcdiv, vmcdiv DOUBLE COMPLEX, INTENT(IN) for vzdiv, vmzdiv C: const float* for vsDiv, vmsDiv const double* for vdDiv, vmdDiv const MKL_Complex8* for vcDiv, vmcDiv const MKL_Complex16* for vzDiv, vmzDiv	FORTRAN: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Div Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{FLT_MAX}$
double precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{DBL_MAX}$

Precision overflow thresholds for the complex v?Div function are beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsdiv, vmsdiv DOUBLE PRECISION for vddiv, vmddiv COMPLEX for vcdiv, vmcddiv DOUBLE COMPLEX for vzdiv, vmzdiv Fortran 90: REAL, INTENT (OUT) for vsdiv, vmsdiv DOUBLE PRECISION, INTENT (OUT) for vddiv, vmddiv COMPLEX, INTENT (OUT) for vcdiv, vmcddiv DOUBLE COMPLEX, INTENT (OUT) for vzdiv, vmzdiv C: float* for vsDiv, vmsDiv double* for vdDiv, vmdDiv MKL_Complex8* for vcDiv, vmcDiv MKL_Complex16* for vzDiv, vmzDiv	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The v?Div function performs element by element division of vector *a* by vector *b*.

Special values for Real Function v?Div(x)

Argument 1	Argument 2	Result	VML Error Status	Exception
X > +0	+0	+∞	VML_STATUS_SING	ZERODIVIDE
X > +0	-0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	+0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	-0	+∞	VML_STATUS_SING	ZERODIVIDE

Argument 1	Argument 2	Result	VML Error Status	Exception
+0	+0	QNAN	VML_STATUS_SING	
-0	-0	QNAN	VML_STATUS_SING	
X > +0	+∞	+0		
X > +0	-∞	-0		
+∞	+∞	QNAN		
-∞	-∞	QNAN		
QNAN	QNAN	QNAN		
SNAN	SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Div}(x_1+i*y_1, x_2+i*y_2) = (x_1+i*y_1)*(x_2-i*y_2) / (x_2*x_2+y_2*y_2).$$

Overflow in a complex function occurs when x_2+i*y_2 is not zero, x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Sqrt

Computes a square root of vector elements.

Syntax

Fortran:

```
call vssqrt( n, a, y )
call vmssqrt( n, a, y, mode )
call vdsqrt( n, a, y )
call vmdsqrt( n, a, y, mode )
call vc_sqrt( n, a, y )
call vmc_sqrt( n, a, y, mode )
call vzsqrt( n, a, y )
call vmzsqrt( n, a, y, mode )
```

C:

```
vsqrt( n, a, y );
vmsqrt( n, a, y, mode );
vd_sqrt( n, a, y );
vmd_sqrt( n, a, y, mode );
vc_sqrt( n, a, y );
vmc_sqrt( n, a, y, mode );
vzsqrt( n, a, y );
vmzsqrt( n, a, y, mode );
```

	MKL_Complex16* for vzSqrt, vmzSqrt	

Description

The v?Sqrt function computes a square root of vector elements.

Special Values for Real Function v?Sqrt(x)

Argument	Result	VML Error Status	Exception
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Sqrt(z)

RE(z) i·IM(z)	-∞	-x	-0	+0	+x	+∞	NAN
+i·∞	+∞+i·∞						
+i·Y	+0+i·∞					+0+i·0	QNAN+i·QNAN
+i·0	+0+i·∞		+0+i·0	+0+i·0		+0+i·0	QNAN+i·QNAN
-i·0	+0-i·∞		+0-i·0	+0-i·0		+0-i·0	QNAN+i·QNAN
-i·Y	+0-i·∞					+0-i·0	QNAN+i·QNAN
-i·∞	+∞-i·∞						

RE(z)	-∞	-X	-0	+0	+X	+∞	NAN
i·IM(z)							
+i·NAN N	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises INVALID exception when the real or imaginary part of the argument is SNAN
- $\text{Sqrt}(\text{CONJ}(z)) = \text{CONJ}(\text{Sqrt}(z))$.

v?InvSqrt

Computes an inverse square root of vector elements.

Syntax

Fortran:

```
call vsinvsqrt( n, a, y )
call vmsinvsqrt( n, a, y, mode )
call vdinvsqrt( n, a, y )
call vmdinvsqrt( n, a, y, mode )
```

C:

```
vsInvSqrt( n, a, y );
vmsInvSqrt( n, a, y, mode );
vdInvSqrt( n, a, y );
vmdInvSqrt( n, a, y, mode );
```

y	FORTRAN 77: REAL for vspow2o3, vmspov2o3 DOUBLE PRECISION for vdpow2o3, vmdpow2o3 Fortran 90: REAL, INTENT(OUT) for vspow2o3, vmspov2o3 DOUBLE PRECISION, INTENT(OUT) for vdpow2o3, vmdpow2o3 C: float* for vsPow2o3, vmsPow2o3 double* for vdPow2o3, vmdPow2o3	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Pow2o3` function raises each element of a vector to the constant power 2/3.

Special Values for Real Function `v?Pow2o3(x)`

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

`v?Pow3o2`

Raises each element of a vector to the constant power 3/2.

Syntax

Fortran:

```
call vspow3o2( n, a, y )
```

```
call vmspow3o2( n, a, y, mode )
call vdpow3o2( n, a, y )
call vmdpow3o2( n, a, y, mode )
```

C:

```
vsPow3o2( n, a, y );
vmsPow3o2( n, a, y, mode );
vdPow3o2( n, a, y );

SNAN	QNAN		INVALID

v?Pow

Computes *a* to the power *b* for elements of two vectors.

Syntax

Fortran:

```

call vspow( n, a, b, y )
call vmspown( n, a, b, y, mode )
call vdPow( n, a, b, y )
call vmdPow( n, a, b, y, mode )
call vcPow( n, a, b, y )
call vmcPow( n, a, b, y, mode )
call vzPow( n, a, b, y )
call vmzPow( n, a, b, y, mode )

```

C:

```

vsPow( n, a, b, y );
vmsPow( n, a, b, y, mode );

```

```
vdPow( n, a, b, y );
vmdPow( n, a, b, y, mode );
vcPow( n, a, b, y );
vmcPow( n, a, b, y, mode );
vzPow( n, a, b, y );
vmzPow( n, a, b, y, mode );
```

Precision Overflow Thresholds for Real v?Pow Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT_MAX})^{1/b[i]}$
double precision	$\text{abs}(a[i]) < (\text{DBL_MAX})^{1/b[i]}$

Precision overflow thresholds for the complex v?Pow function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vspow, vmspow DOUBLE PRECISION for vdpow, vmdpow COMPLEX for vcpow, vmcpow DOUBLE COMPLEX for vzpow, vmzpow Fortran 90: REAL, INTENT(OUT) for vspow, vmspow DOUBLE PRECISION, INTENT(OUT) for vdpow, vmdpow COMPLEX, INTENT(OUT) for vcPow, vmcpow DOUBLE COMPLEX, INTENT(OUT) for vzpow, vmzpow C: float* for vsPow, vmsPow double* for vdPow, vmdPow MKL_Complex8* for vcPow, vmcpow MKL_Complex16* for vzPow, vmzPow	FORTRAN: Array that specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

The v?Pow function computes a to the power b for elements of two vectors.

The real function v(s/d) Pow has certain limitations on the input range of a and b parameters. Specifically, if $a[i]$ is positive, then $b[i]$ may be arbitrary. For negative $a[i]$, the value of $b[i]$ must be an integer (either positive or negative).

The complex function v(c/z) Pow has no input range limitations.

Special values for Real Function v?Pow(x)

SNAN	SNAN	QNAN		INVALID

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1, x_2, y_1, y_2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Powx

Raises each element of a vector to the constant power.

Syntax

Fortran:

```
call vspowx( n, a, b, y )
call vmspowx( n, a, b, y, mode )
call vdpowx( n, a, b, y )
call vmdpowx( n, a, b, y, mode )
call vcpowx( n, a, b, y )
call vmcpowx( n, a, b, y, mode )
call vzpowx( n, a, b, y )
call vmzpowx( n, a, b, y, mode )
```

C:

```
vsPowx( n, a, b, y );
vmsPowx( n, a, b, y, mode );
vdPowx( n, a, b, y );
vmdPowx( n, a, b, y, mode );
vcPowx( n, a, b, y );
vmcPowx( n, a, b, y, mode );
vzPowx( n, a, b, y );
vmzPowx( n, a, b, y, mode );
```

Precision Overflow Thresholds for Real v?Powx Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT_MAX})^{1/b}$
double precision	$\text{abs}(a[i]) < (\text{DBL_MAX})^{1/b}$

Precision overflow thresholds for the complex v?Powx function are beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vspowx, vmspowl	FORTRAN: Array that specifies the output vector <i>y</i> .
	DOUBLE PRECISION for vdpowx, vmdpowx	C: Pointer to an array that contains the output vector <i>y</i> .
	COMPLEX for vcPowx, vmcpowx	
	DOUBLE COMPLEX for vzpowx, vmzpowx	
	Fortran 90: REAL, INTENT(OUT) for vspowx, vmspowl	
	DOUBLE PRECISION, INTENT(OUT) for vdpowx, vmdpowx	
	COMPLEX, INTENT(OUT) for vcPowx, vmcpowx	
	DOUBLE COMPLEX, INTENT(OUT) for vzpowx, vmzpowx	

Name	Type	Description
	C: float* for vsPowx, vmsPowx double* for vdPowx, vmdPowx MKL_Complex8* for vcPowx, vmcPowx MKL_Complex16* for vzPowx, vmzPowx	

Description

The `v?Powx` function raises each element of a vector to the constant power.

The real function `v(s/d) Powx` has certain limitations on the input range of `a` and `b` parameters. Specifically, if `a[i]` is positive, then `b` may be arbitrary. For negative `a[i]`, the value of `b` must be an integer (either positive or negative).

The complex function `v(c/z) Powx` has no input range limitations.

Special values are the same as for the `v?Pow` function.

v?Hypot

Computes a square root of sum of two squared elements.

Syntax

Fortran:

```
call vshypot( n, a, b, y )
call vmshypot( n, a, b, y, mode )
call vdhypot( n, a, b, y )
call vmdhypot( n, a, b, y, mode )
```

C:

```
vsHypot( n, a, b, y );
vmsHypot( n, a, b, y, mode );
vdHypot( n, a, b, y );
vmdHypot( n, a, b, y, mode );
```

Description

The v?Exp function computes an exponential of vector elements.

Special Values for Real Function v?Exp(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
+∞	+∞		
-∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Exp(z)

RE(z)	-∞	-x	-0	+0	+x	+∞	NAN
i·IM(z)							
+i·∞	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID
+i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	+0·CIS(0)		+1+i·0	+1+i·0		+∞+i·0	QNAN+i·0

RE(z)	-∞	-X	-0	+0	+X	+∞	NAN
i·IM(z)							
-i·0	+0·CIS(0)		+1-i·0	+1-i·0		+∞-i·0	QNAN-i·0
-i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	+0-i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when real or imaginary part of the argument is `SNAN`
- raises the `INVALID` exception on argument $z=-\infty+i\cdot\text{QNAN}$
- raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when $\text{RE}(z)$, $\text{IM}(z)$ are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

v?Expm1

Computes an exponential of vector elements decreased by 1.

Syntax

Fortran:

```
call vsexpm1( n, a, y )
call vmsexpm1( n, a, y, mode )
call vdexpml( n, a, y )
call vdmexpml( n, a, y, mode )
```

C:

```
vsExpm1( n, a, y );
vmsExpm1( n, a, y, mode );
vdExpml( n, a, y );
vmdExpml( n, a, y, mode );
```

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN

v?Log10

Computes denary logarithm of vector elements.

Syntax

Fortran:

```
call vslog10( n, a, y )
call vmslog10( n, a, y, mode )
call vdlog10( n, a, y )
call vmdlog10( n, a, y, mode )
call vclog10( n, a, y )
call vmclog10( n, a, y, mode )
call vzlog10( n, a, y )
call vmzlog10( n, a, y, mode )
```

C:

```
vsLog10( n, a, y );
vmsLog10( n, a, y, mode );
vdLog10( n, a, y );
vmdLog10( n, a, y, mode );
vcLog10( n, a, y );
vmcLog10( n, a, y, mode );
vzLog10( n, a, y );
vmzLog10( n, a, y, mode );
```

Include Files

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN

v?Log1p

Computes a natural logarithm of vector elements that are increased by 1.

Syntax

Fortran:

```
call vslog1p( n, a, y )
call vmslog1p( n, a, y, mode )
call vdlog1p( n, a, y )
call vmdlog1p( n, a, y, mode )
```

C:

```
vsLog1p( n, a, y );
vmsLog1p( n, a, y, mode );
vdLog1p( n, a, y );
vmdLog1p( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vslog1p, vmslog1p DOUBLE PRECISION for vdlog1p, vmdlog1p Fortran 90: REAL, INTENT (IN) for vslog1p, vmslog1p DOUBLE PRECISION, INTENT (IN) for vdlog1p, vmdlog1p C: const float* for vsLog1p, vmsLog1p const double* for vdLog1p, vmdLog1p	FORTRAN: Array that specifies the input vector a . C: Pointer to an array that contains the input vector a .
$mode$	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vslog1p, vmslog1p DOUBLE PRECISION for vdlog1p, vmdlog1p Fortran 90: REAL, INTENT (OUT) for vslog1p, vmslog1p DOUBLE PRECISION, INTENT (OUT) for vdlog1p, vmdlog1p C: float* for vsLog1p, vmsLog1p double* for vdLog1p, vmdLog1p	FORTRAN: Array that specifies the output vector y . C: Pointer to an array that contains the output vector y .

Description

The $v?Log1p$ function computes a natural logarithm of vector elements that are increased by 1.

Special Values for Real Function $v?Log1p(x)$

Argument	Result	VML Error Status	Exception
-1	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$x < -1$	QNAN	VML_STATUS_ERRDOM	INVALID

$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

Trigonometric Functions

v?Cos

Computes cosine of vector elements.

Syntax

Fortran:

```
call vscos( n, a, y )
call vmscos( n, a, y, mode )
call vdcos( n, a, y )
call vmdcos( n, a, y, mode )
call vccos( n, a, y )
call vmccos( n, a, y, mode )
call vzcos( n, a, y )
call vmzcos( n, a, y, mode )
```

C:

```
vsCos( n, a, y );
vmsCos( n, a, y, mode );
vdCos( n, a, y );
vmdCos( n, a, y, mode );
vcCos( n, a, y );
vmcCos( n, a, y, mode );
vzCos( n, a, y );
vmzCos( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vscos, vmscos DOUBLE PRECISION for vdcos, vmdcos COMPLEX for vccos, vmccos DOUBLE PRECISION for vzcos, vmzcos Fortran 90: REAL, INTENT (IN) for vscos, vmscos DOUBLE PRECISION, INTENT (IN) for vdcos, vmdcos COMPLEX, INTENT (IN) for vccos, vmccos DOUBLE PRECISION, INTENT (IN) for vzcos, vmzcos C: const float* for vsCos, vmsCos const double* for vdCos, vmdCos const MKL_Complex8* for vcCos, vmcCos const MKL_Complex16* for vzCos, vmzCos	FORTRAN: Array that specifies the input vector <i>a</i> . <i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vscos, vmscos DOUBLE PRECISION for vdcos, vmdcos COMPLEX for vccos, vmccos DOUBLE PRECISION for vzcos, vmzcos	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	<p>Fortran 90: REAL, INTENT(OUT) for vscos, vmscos</p> <p>DOUBLE PRECISION, INTENT(OUT) for vdcos, vmdcos</p> <p>COMPLEX, INTENT(OUT) for vccos, vmccos</p> <p>DOUBLE PRECISION, INTENT(OUT) for vzcos, vmzcos</p> <p>C: float* for vsCos, vmsCos double* for vdCos, vmdCos MKL_Complex8* for vcCos, vmcCos MKL_Complex16* for vzCos, vmzCos</p>	

Description

The v?Cos function computes cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Cos(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Cos}(z) = \text{Cosh}(i \cdot z).$$

v?Sin

Computes sine of vector elements.

Syntax

Fortran:

```
call vssin( n, a, y )
call vmssin( n, a, y, mode )
call vdsin( n, a, y )
call vmdsin( n, a, y, mode )
call vcsin( n, a, y )
call vmcsin( n, a, y, mode )
```

```
call vzsIn( n, a, y )
call vmzsIn( n, a, y, mode )
```

C:

```
vsSin( n, a, y );
vmsSin( n, a, y, mode );
vdSin( n, a, y );
vmdSin( n, a, y, mode );
vcSin( n, a, y );
vmcSin( n, a, y, mode );
vzSin( n, a, y );
vmzSin( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description

a	FORTRAN 77: REAL for vssin, vmssin DOUBLE PRECISION for vdsin, vmdsin COMPLEX for vcsin, vmcsin DOUBLE PRECISION for vzsIn, vmzsIn Fortran 90: REAL, INTENT(IN) for vssin, vmssin DOUBLE PRECISION, INTENT(IN) for vdsin, vmdsin COMPLEX, INTENT(IN) for vcsin, vmcsin DOUBLE PRECISION, INTENT(IN) for vzsIn, vmzsIn C: const float* for vsSin, vmsSin const double* for vdSin, vmdSin const MKL_Complex8* for vcSin, vmcSin	FORTRAN: Array that specifies the input vector a. C: Pointer to an array that contains the input vector a.

Name	Type	Description
	const MKL_Complex16* for vzSin, vmzSin	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vssin, vmssin DOUBLE PRECISION for vdsin, vmdsin COMPLEX for vcsin, vmcsin DOUBLE PRECISION for vzsin, vmzsin Fortran 90: REAL, INTENT (OUT) for vssin, vmssin DOUBLE PRECISION, INTENT (OUT) for vdsin, vmdsin COMPLEX, INTENT (OUT) for vcsin, vmcsin DOUBLE PRECISION, INTENT (OUT) for vzsin, vmzsin C: float* for vsSin, vmsSin double* for vdSin, vmdSin MKL_Complex8* for vcSin, vmcSin MKL_Complex16* for vzSin, vmzSin	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.f90` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Sin(x)

Argument	Result	VML Error Status	Exception
+0	+0		

Argument	Result	VML Error Status	Exception
-0	-0		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Sin}(z) = -i \cdot \text{Sinh}(i \cdot z).$$

v?SinCos

Computes sine and cosine of vector elements.

Syntax

Fortran:

```
call vssincos( n, a, y, z )
call vmssincos( n, a, y, z, mode )
call vdsincos( n, a, y, z )
call vmdsincos( n, a, y, z, mode )
```

C:

```
vsSinCos( n, a, y, z );
vmsSinCos( n, a, y, z, mode );
vdSinCos( n, a, y, z );
vmdSinCos( n, a, y, z, mode );
```

Include Files

y, z	FORTRAN 77: REAL for vssincos, vmssincos DOUBLE PRECISION for vdsincos, vmdsincos Fortran 90: REAL, INTENT(OUT) for vssincos, vmssincos DOUBLE PRECISION, INTENT(OUT) for vdsincos, vmdsincos C: float* for vsSinCos, vmsSinCos double* for vdSinCos, vmdSinCos	FORTRAN: Arrays that specify the output vectors y (for sine values) and z (for cosine values). C: Pointers to arrays that contain the output vectors y (for sinevalues) and z (for cosine values).

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.f90` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine and cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?SinCos(x)

Argument	Result 1	Result 2	VML Error Status	Exception
+0	+0	+1		
-0	-0	+1		
$+\infty$	QNAN	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN	QNAN		
SNAN	QNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Sin(z) = -i*Sinh(i*z).`

v?CIS

*Computes complex exponent of real vector elements
(cosine and sine of real vector elements combined to
complex value).*

Syntax

Fortran:

```
call vccis( n, a, y )
call vmccis( n, a, y, mode )
call vzcis( n, a, y )
call vmzcis( n, a, y, mode )
```

C:

```
vccCIS( n, a, y );
vmcCIS( n, a, y, mode );
vzCIS( n, a, y );
vmzCIS( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vccis, vmccis DOUBLE PRECISION for vzcis, vmzcis Fortran 90: REAL, INTENT(IN) for vccis, vmccis DOUBLE PRECISION, INTENT(IN) for vzcis, vmzcis C: const float* for vcCIS, vmcCIS const double* for vzCIS, vmzCIS	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Name	Type	Description
	Fortran 90: INTEGER (KIND=8), INTENT (IN)	
	C: const MKL_INT64	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: COMPLEX for vccis, vmccis DOUBLE COMPLEX for vzcis, vmzcis Fortran 90: COMPLEX, INTENT (OUT) for vccis, vmccis DOUBLE COMPLEX, INTENT (OUT) for vzcis, vmzcis	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	C: MKL_Complex8* for vcCIS, vmcCIS MKL_Complex16* for vzCIS, vmzCIS	

Description

The `v?CIS` function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function `v?CIS(x)`

x	CIS(x)
+ ∞	QNAN+i·QNAN INVALID
+ 0	+1+i·0
- 0	+1-i·0
- ∞	QNAN+i·QNAN INVALID
NAN	QNAN+i·QNAN

Notes:

- raises INVALID exception when the argument is SNAN
- raises INVALID exception and sets the VML Error Status to VML_STATUS_ERRDOM for $x=+\infty$, $x=-\infty$

v?Tan

Computes tangent of vector elements.

Syntax

Fortran:

```
call vstan( n, a, y )
call vmstan( n, a, y, mode )
call vdtan( n, a, y )
call vmdtan( n, a, y, mode )
call vctan( n, a, y )
call vmctan( n, a, y, mode )
call vztan( n, a, y )
call vmztan( n, a, y, mode )
```

C:

```
vsTan( n, a, y );
vmsTan( n, a, y, mode );
vdTan( n, a, y );
vmdTan( n, a, y, mode );
vcTan( n, a, y );
vmcTan( n, a, y, mode );
vzTan( n, a, y );
vmzTan( n, a, y, mode );
```

Include Files

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vstan, vmstan DOUBLE PRECISION for vdtan, vmdtan COMPLEX for vctan, vmctan DOUBLE COMPLEX for vztan, vmztan	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT(OUT) for vstan, vmstan DOUBLE PRECISION, INTENT(OUT) for vdtan, vmdtan COMPLEX, INTENT(OUT) for vctan, vmctan DOUBLE COMPLEX, INTENT(OUT) for vztan, vmztan	
	C: float* for vsTan, vmsTan double* for vdTan, vmdTan MKL_Complex8* for vcTan, vmcTan MKL_Complex16* for vzTan, vmzTan	

Description

The v?Tan function computes tangent of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Tan(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Tan}(z) = -i \cdot \text{Tanh}(i \cdot z).$$

v?Acos

Computes inverse cosine of vector elements.

Syntax

Fortran:

```
call vsacos( n, a, y )
call vmsacos( n, a, y, mode )
call vdacos( n, a, y )
call vmdacos( n, a, y, mode )
call vcacos( n, a, y )
call vmcacos( n, a, y, mode )
call vzacos( n, a, y )
call vmzacos( n, a, y, mode )
```

C:

```
vsAcos( n, a, y );
vmsAcos( n, a, y, mode );
vdAcos( n, a, y );
vmdAcos( n, a, y, mode );
vcAcos( n, a, y );
vmcacos( n, a, y, mode );
vzAcos( n, a, y );
vmzacos( n, a, y, mode );
```

	MKL_Complex8* for vcAcos, vmcAcos	
	MKL_Complex16* for vzAcos, vmzAcos	

Description

The v?Acos function computes inverse cosine of vector elements.

Special Values for Real Function v?Acos(x)

Argument	Result	VML Error Status	Exception
+0	+π/2		
-0	+π/2		
+1	+0		
-1	+π		
X > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Acos(z)

RE(z)	-∞	-X	-0	+0	+X	+∞	NAN
i·IM(z)							
+i·∞	$+\frac{3\pi}{4} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{4} - i \cdot \infty$	QNAN-i·∞			
+i·Y	+π-i·∞					+0-i·∞	QNAN+i·QNAN
+i·0	+π-i·∞		$+\frac{\pi}{2} - i \cdot 0$	$+\frac{\pi}{2} - i \cdot 0$		+0-i·∞	QNAN+i·QNAN

RE(z)	-∞	-x	-0	+0	+x	+∞	NAN
i·IM(z)							
-i·0	+π+i·∞		$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$		+0+i·∞	QNAN+i·QNAN
-i·Y	+π+i·∞					+0+i·∞	QNAN+i·QNAN
-i·∞	$+\frac{3\pi}{4} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{4} + i \cdot \infty$	QNAN+i·∞
+i·NAN	QNAN+i·∞	QNAN+i·QNAN	$+\frac{\pi}{2} + i \cdot \text{QNAN}$	$+\frac{\pi}{2} + i \cdot \text{QNAN}$	QNAN+i·QNAN	QNAN+i·∞	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- $\text{Acos}(\text{CONJ}(z)) = \text{CONJ}(\text{Acos}(z))$.

v?Asin

Computes inverse sine of vector elements.

Syntax

Fortran:

```
call vsasin( n, a, y )
call vmsasin( n, a, y, mode )
call vdasin( n, a, y )
call vmdasin( n, a, y, mode )
call vcasin( n, a, y )
call vmcasin( n, a, y, mode )
call vzasin( n, a, y )
call vmzasin( n, a, y, mode )
```

C:

```
vsAsin( n, a, y );
vmsAsin( n, a, y, mode );
vdAsin( n, a, y );
vmdAsin( n, a, y, mode );
vcAsin( n, a, y );
vmcAsin( n, a, y, mode );
vzAsin( n, a, y );
vmzAsin( n, a, y, mode );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vml.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.

C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsasin, vmsasin DOUBLE PRECISION for vdasin, vmdasin COMPLEX for vcasin, vmcasin	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	DOUBLE COMPLEX for vzasin, vmzasin	
	Fortran 90: REAL, INTENT(OUT) for vsasin, vmsasin	
	DOUBLE PRECISION, INTENT(OUT) for vdasin, vmdasin	
	COMPLEX, INTENT(OUT) for vcasin, vmcasin	
	DOUBLE COMPLEX, INTENT(OUT) for vzasin, vmzasin	
	C: float* for vsAsin, vmsAsin double* for vdAsin, vmdAsin	
	MKL_Complex8* for vcAsin, vmcAsin	
	MKL_Complex16* for vzAsin, vmzAsin	

Description

The v?Asin function computes inverse sine of vector elements.

Special Values for Real Function v?Asin(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+1	+π/2		
-1	-π/2		
X > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Asin}(z) = -i \cdot \text{Asinh}(i \cdot z).$$

v?Atan

Computes inverse tangent of vector elements.

Syntax

Fortran:

```
call vsatan( n, a, y )
call vmsatan( n, a, y, mode )
call vdatan( n, a, y )
call vmdata( n, a, y, mode )
```

```
call vcatan( n, a, y )
call vmcatan( n, a, y, mode )
call vzatan( n, a, y )
call vmzatan( n, a, y, mode )
```

C:

```
vsAtan( n, a, y );
vmsAtan( n, a, y, mode );
vdAtan( n, a, y );
vmdAtan( n, a, y, mode );
vcAtan( n, a, y );
vmcAtan( n, a, y, mode );
vzAtan( n, a, y );
vmzAtan( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vsatan, vmsatan DOUBLE PRECISION for vdatan, vmdataan COMPLEX for vc atan, vmcatan DOUBLE COMPLEX for vzatan, vmzatan Fortran 90: REAL, INTENT(IN) for vsatan, vmsatan DOUBLE PRECISION, INTENT(IN) for vdatan, vmdataan COMPLEX, INTENT(IN) for vc atan, vmcatan DOUBLE COMPLEX, INTENT(IN) for vzatan, vmzatan C: const float* for vsAtan, vmsAtan	FORTRAN: Array that specifies the input vector a. C: Pointer to an array that contains the input vector a.

Name	Type	Description
	const double* for vdAsin, vmdAtan const MKL_Complex8* for vcAtan, vmcAtan const MKL_Complex16* for vzAsin, vmzAtan	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsatan, vmsatan DOUBLE PRECISION for vdatan, vmdatn COMPLEX for vcatan, vmcatan DOUBLE COMPLEX for vzatan, vmzatan Fortran 90: REAL, INTENT (OUT) for vsatan, vmsatan DOUBLE PRECISION, INTENT (OUT) for vdatan, vmdatn COMPLEX, INTENT (OUT) for vcatan, vmcatan DOUBLE COMPLEX, INTENT (OUT) for vzatan, vmzatan C: float* for vsAtan, vmsAtan double* for vdAsin, vmdAtan MKL_Complex8* for vcAtan, vmcAtan MKL_Complex16* for vzAsin, vmzAtan	FORTRAN: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The v?Atan function computes inverse tangent of vector elements.

Special Values for Real Function v?Atan(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+∞	+π/2		

Argument	Result	VML Error Status	Exception
-∞	-π/2		
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Atan}(z) = -i \cdot \text{Atanh}(i \cdot z).$$

v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

Fortran:

```
call vsatan2( n, a, b, y )
call vmsatan2( n, a, b, y, mode )
call vdatan2( n, a, b, y )
call vmdatan2( n, a, b, y, mode )
```

C:

```
vsAtan2( n, a, b, y );
vmsAtan2( n, a, b, y, mode );
vdAtan2( n, a, b, y );
vmdAtan2( n, a, b, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
<i>a, b</i>	FORTRAN 77: REAL for vsatan2, vmsatan2 DOUBLE PRECISION for vdatan2, vmdatan2 Fortran 90: REAL, INTENT(IN) for vsatan2, vmsatan2 DOUBLE PRECISION, INTENT(IN) for vdatan2, vmdatan2	FORTRAN: Arrays that specify the input vectors <i>a</i> and <i>b</i> . C: Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .

Name	Type	Description
	C: const float* for vsAtan2, vmsAtan2 const double* for vdAtan2, vmdAtan2	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Atan2` function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector are computed as the four-quadrant arctangent of $a[i] / b[i]$.

C: Pointer to an array that contains the input vector a.

Name	Type	Description
	const double* for vdCosh, vmdCosh const MKL_Complex8* for vcCosh, vmcCosh const MKL_Complex16* for vzCosh, vmzCosh	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Cosh Function

Data Type	Threshold Limitations on Input Parameters
single precision	-Ln (FLT_MAX)-Ln2 < a[i] < Ln (FLT_MAX)+Ln2
double precision	-Ln (DBL_MAX)-Ln2 < a[i] < Ln (DBL_MAX)+Ln2

Precision overflow thresholds for the complex v?Cosh function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vscosh, vmscosh DOUBLE PRECISION for vdCosh, vmdCosh COMPLEX for vcCosh, vmcCosh DOUBLE COMPLEX for vzCosh, vmzCosh Fortran 90: REAL, INTENT (OUT) for vscosh, vmscosh DOUBLE PRECISION, INTENT (OUT) for vdCosh, vmdCosh COMPLEX, INTENT (OUT) for vcCosh, vmcCosh DOUBLE COMPLEX, INTENT (OUT) for vzCosh, vmzCosh C: float* for vsCosh, vmsCosh double* for vdCosh, vmdCosh MKL_Complex8* for vcCosh, vmcCosh MKL_Complex16* for vzCosh, vmzCosh	FORTRAN: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The v?Cosh function computes hyperbolic cosine of vector elements.

Special Values for Real Function v?Cosh(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < -overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Cosh(z)

RE(z) i·IM(z)	-∞	-x	-0	+0	+x	+∞	NAN
+i·∞	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN-i·0 INVALID	QNAN+i·0 INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·Y	+∞·Cos(Y)- i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	+∞-i·0		+1-i·0	+1+i·0		+∞+i·0	QNAN+i·0
-i·0	+∞+i·0		+1+i·0	+1-i·0		+∞-i·0	QNAN-i·0
-i·Y	+∞·Cos(Y)- i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·0 INVALID	QNAN-i·0 INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	+∞+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN-i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the INVALID exception when the real or imaginary part of the argument is SNAN
- raises the OVERFLOW exception and sets the VML Error Status to VML_STATUS_OVERFLOW in the case of overflow, that is, when RE(z), IM(z) are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\text{Cosh}(\text{CONJ}(z)) = \text{CONJ}(\text{Cosh}(z))$
- $\text{Cosh}(-z) = \text{Cosh}(z)$.

v?Sinh

Computes hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vssinh( n, a, y )
call vmssinh( n, a, y, mode )
call vdsinh( n, a, y )
call vmdsinh( n, a, y, mode )
call vcsinh( n, a, y )
call vmcsinh( n, a, y, mode )
call vzsinh( n, a, y )
call vmzsinh( n, a, y, mode )
```

C:

```
vsSinh( n, a, y );
vmsSinh( n, a, y, mode );
vdSinh( n, a, y );
vmdSinh( n, a, y, mode );
vcSinh( n, a, y );
vmcSinh( n, a, y, mode );
vzSinh( n, a, y );
vmzSinh( n, a, y, mode );
```

QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v?Sinh(z)$

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	-∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	-0+i·QNAN INVALID	+0+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·Y	-∞·Cos(Y)+ i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	-∞+i·0		-0+i·0	+0+i·0		+∞+i·0	QNAN+i·0
-i·0	-∞-i·0		-0-i·0	+0-i·0		+∞-i·0	QNAN-i·0
-i·Y	-∞·Cos(Y)+ i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	-∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	-0+i·QNAN INVALID	+0+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	-∞+i·QNAN	QNAN+i·QNAN	-0+i·QNAN	+0+i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the INVALID exception when the real or imaginary part of the argument is SNAN

- raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when `RE(z)`, `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\text{Sinh}(\text{CONJ}(z)) = \text{CONJ}(\text{Sinh}(z))$
- $\text{Sinh}(-z) = -\text{Sinh}(z)$.

v?Tanh

Computes hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vstanh( n, a, y )
call vmstanh( n, a, y, mode )
call vdttanh( n, a, y )
call vmdtanh( n, a, y, mode )
call vctanh( n, a, y )
call vmctanh( n, a, y, mode )
call vzttanh( n, a, y )
call vmztanh( n, a, y, mode )
```

C:

```
vsTanh( n, a, y );
vmsTanh( n, a, y, mode );
vdTanh( n, a, y );
vmdTanh( n, a, y, mode );
vcTanh( n, a, y );
vmcTanh( n, a, y, mode );
vzTanh( n, a, y );
vmzTanh( n, a, y, mode );
```

Include Files

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- $\text{Tanh}(\text{CONJ}(z)) = \text{CONJ}(\text{Tanh}(z))$
- $\text{Tanh}(-z) = -\text{Tanh}(z)$.

v?Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

Fortran:

```
call vsacosh( n, a, y )
call vmsacosh( n, a, y, mode )
call vdacosh( n, a, y )
call vmdacosh( n, a, y, mode )
call vcacosh( n, a, y )
call vmcacosh( n, a, y, mode )
call vzacosh( n, a, y )
call vmzacosh( n, a, y, mode )
```

C:

```
vsAcosh( n, a, y );
vmsAcosh( n, a, y, mode );
vdAcosh( n, a, y );
vmdAcosh( n, a, y, mode );
vcAcosh( n, a, y );
vmcAcosh( n, a, y, mode );
vzAcosh( n, a, y );
vmzAcosh( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
n	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Specifies the number of elements to be calculated.
a	FORTRAN 77: REAL for vsacosh, vmsacosh DOUBLE PRECISION for vdacosh, vmdacosh COMPLEX for vcacosh, vmcacosh	FORTRAN: Array that specifies the input vector a. C: Pointer to an array that contains the input vector a.

Name	Type	Description
	DOUBLE COMPLEX for vzacosh, vmzacosh

Notes:

- Atanh (+-1+-i*0) = +-∞+-i*0, and ZERODIVIDE exception is raised
- raises INVALID exception when real or imaginary part of the argument is SNAN
- Atanh (CONJ(z)) = CONJ(Atanh(z))
- Atanh (-z) = -Atanh (z).

Special Functions**v?Erf**

Computes the error function value of vector elements.

Syntax**Fortran:**

```
call vserf( n, a, y )
call vmserf( n, a, y, mode )
call vderf( n, a, y )
```

```
call vmderf( n, a, y, mode )
```

C:

```
vsErf( n, a, y );
vmsErf( n, a, y, mode );
vdErf( n, a, y );
vmdErf( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserf, vmserf DOUBLE PRECISION for vderf, vmderf Fortran 90: REAL, INTENT(IN) for vserf, vmserf DOUBLE PRECISION, INTENT(IN) for vderf, vmderf C: const float* for vsErf, vmsErf const double* for vdErf, vmdErf	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vserf, vmserf DOUBLE PRECISION for vderf, vmderf Fortran 90: REAL, INTENT(OUT) for vserf, vmserf	FORTRAN: Array, specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(OUT) for vderf, vmderf	
C: float* for vsErf, vmsErf double* for vdErf, vmdErf		

Description

The `Erf` function computes the error function values for elements of the input vector `a` and writes them to the output vector `y`.

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

1. $\text{erfc}(x) = 1 - \text{erf}(x)$,

where `erfc` is the complementary error function.

2. $\Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2})$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

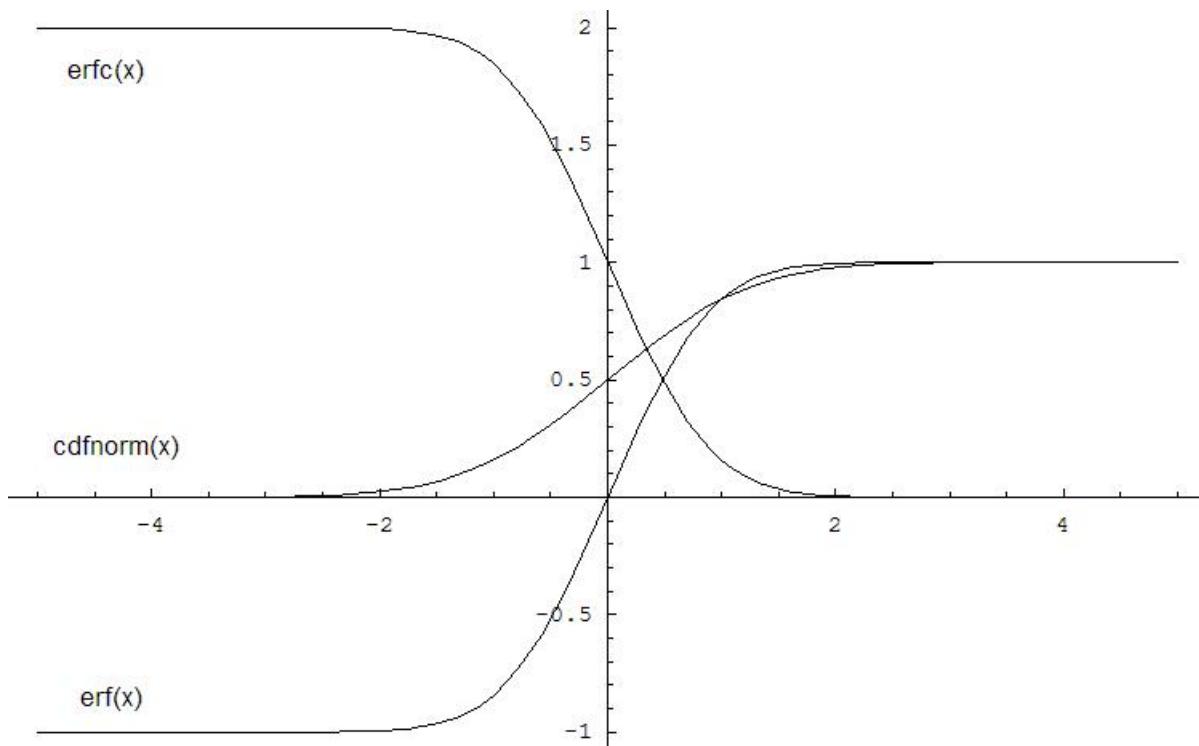

is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1)$,

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

The following figure illustrates the relationships among `Erf` family functions (`Erf`, `Erfc`, `CdfNorm`).

Erf Family Functions Relationship

Useful relations for these functions:

$$\text{erf}(x) + \text{erfc}(x) = 1$$

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$$

Special Values for Real Function v?Erf(x)

Argument	Result	Exception
$+\infty$	+1	
$-\infty$	-1	
QNAN	QNAN	
SNAN	QNAN	INVALID

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vserfc, vmserfc DOUBLE PRECISION for vderfc, vmderfc Fortran 90: REAL, INTENT (IN) for vserfc, vmserfc DOUBLE PRECISION, INTENT (IN) for vderfc, vmderfc C: const float* for vsErfc, vmsErfc const double* for vdErfc, vmdErfc	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vserfc, vmserfc DOUBLE PRECISION for vderfc, vmderfc	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	Fortran 90: REAL, INTENT(OUT) for vserfc, vmserfc	
	DOUBLE PRECISION, INTENT(OUT) for vderfc, vmdervfc	
	C: float* for vsErfc, vmsErfc double* for vdErfc, vmdErfc	

Description

The `Erfc` function computes the complementary error function values for elements of the input vector `a` and writes them to the output vector `y`.

The complementary error function is defined as follows:

$$\text{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt .$$

Useful relations:

1. $\text{erfc}(x) = 1 - \text{erf}(x)$.
2. $\Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2})$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

See also [Figure "Erf Family Functions Relationship"](#) in `Erf` function description for `Erfc` function relationship with the other functions of `Erf` family.

C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `CdfNorm` function computes the cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The cumulative normal distribution function is defined as given by:

$$\text{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt .$$

Useful relations:

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$$

where `Erf` and `Erfc` are the error and complementary error functions.

See also [Figure "Erf Family Functions Relationship"](#) in `Erf` function description for `CdfNorm` function relationship with the other functions of `Erf` family.

y	FORTRAN 77: REAL for vserfinv, vmserfinv DOUBLE PRECISION for vderfinv, vmderfinv Fortran 90: REAL, INTENT (OUT) for vserfinv, vmserfinv DOUBLE PRECISION, INTENT (OUT) for vderfinv, vmderfinv C: float* for vsErfInv, vmsErfInv double* for vdErfInv, vmdErfInv	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `ErfInv` function computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

$$y = \text{erf}^{-1}(a),$$

where `erf(x)` is the error function defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1. \quad \text{erf}^{-1}(x) = \text{erfc}^{-1}(1 - x),$$

where `erfc` is the complementary error function.

$$2. \quad \Phi(x) = \frac{1}{2} \text{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

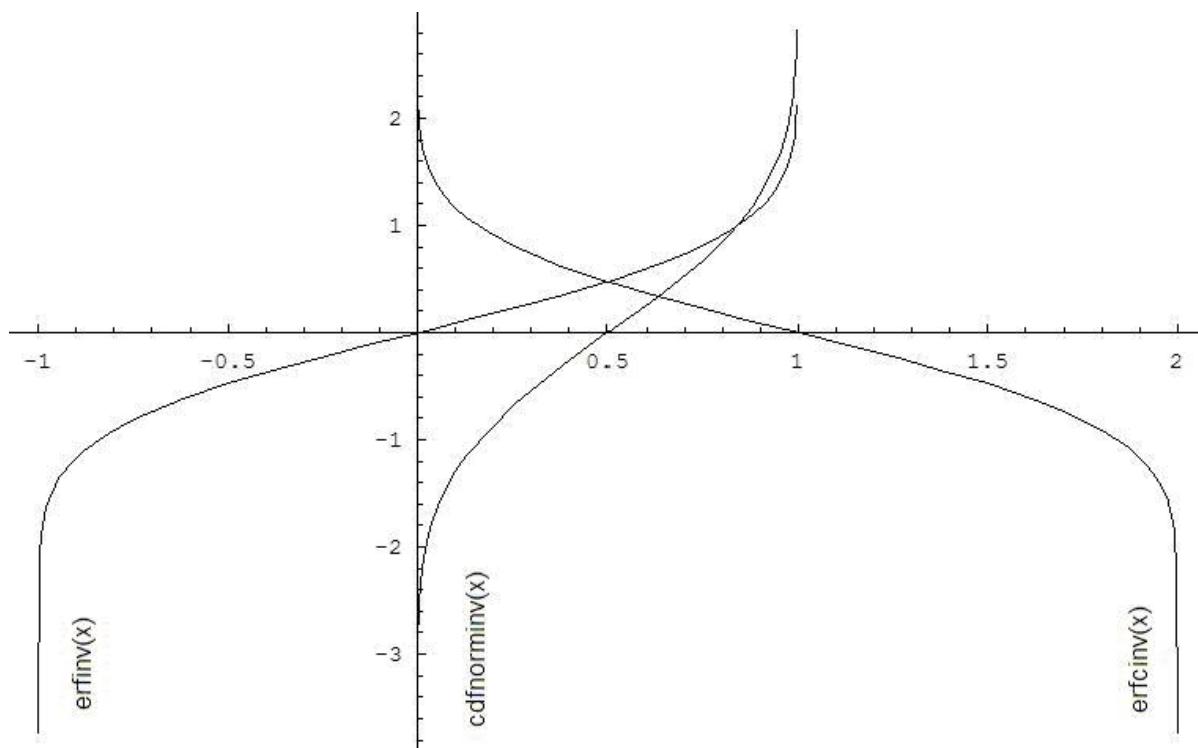

is the cumulative normal distribution function.

$$3. \quad \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

[Figure "ErfInv Family Functions Relationship"](#) illustrates the relationships among `ErfInv` family functions (`ErfInv`, `ErfcInv`, `CdfNormInv`).

ErfInv Family Functions Relationship

Useful relations for these functions:

$$\operatorname{erfcinv}(x) = \operatorname{erfinv}(1 - x)$$

$$\operatorname{cdfnorminv}(x) = \sqrt{2}\operatorname{erfinv}(2x - 1) = \sqrt{2}\operatorname{erfcinv}(2 - 2x)$$

C: Pointer to an array that contains the output vector <i>y</i> .

Description

The `CdfNormInv` function computes the inverse cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse cumulative normal distribution function is defined as given by:

$$\text{CdfNormInv}(x) = \text{CdfNorm}^{-1}(x) ,$$

where `CdfNorm(x)` denotes the cumulative normal distribution function.

Useful relations:

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

where `erfinv(x)` denotes the inverse error function and `erfcinv(x)` denotes the inverse complementary error functions.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsceil, vmsceil DOUBLE PRECISION for vdceil, vmdceil Fortran 90: REAL, INTENT(OUT) for vsceil, vmsceil DOUBLE PRECISION, INTENT(OUT) for vdceil, vmdceil C: float* for vsCeil, vmsceil double* for vdCeil, vmdceil	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The function computes an integer value rounded towards plus infinity for each vector element.

Special Values for Real Function v?Ceil(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Trunc

Computes an integer value rounded towards zero for each vector element.

Syntax

Fortran:

```
call vstrunc( n, a, y )
call vmstrunc( n, a, y, mode )
call vdtrunc( n, a, y )
call vmdtrunc( n, a, y, mode )
```

C:

```
vsTrunc( n, a, y );
vmsTrunc( n, a, y, mode );
vdTrunc( n, a, y );
vmdTrunc( n, a, y, mode );
```

- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vstrunc, vmstrunc DOUBLE PRECISION for vdtrunc, vmdtrunc Fortran 90: REAL, INTENT (IN) for vstrunc, vmstrunc DOUBLE PRECISION, INTENT (IN) for vdtrunc, vmdtrunc C: const float* for vsTrunc, vmstrunc const double* for vdTrunc, vmdtrunc	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vstrunc, vmstrunc DOUBLE PRECISION for vdtrunc, vmdtrunc Fortran 90: REAL, INTENT (OUT) for vstrunc, vmstrunc DOUBLE PRECISION, INTENT (OUT) for vdtrunc, vmdtrunc C: float* for vsTrunc, vmstrunc double* for vdTrunc, vmdtrunc	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Description

The function computes an integer value rounded towards zero for each vector element.

Special Values for Real Function v?Trunc(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Round

Computes a value rounded to the nearest integer for each vector element.

Syntax

Fortran:

```
call vsround( n, a, y )
call vmsround( n, a, y, mode )
call vdround( n, a, y )
call vmdround( n, a, y, mode )
```

C:

```
vsRound( n, a, y );
vmsRound( n, a, y, mode );
vdRound( n, a, y );
vmdRound( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsround, vmsround DOUBLE PRECISION for vdround, vmdround Fortran 90: REAL, INTENT (IN) for vsround, vmsround	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdround, vmdround C: const float* for vsRound, vmsround const double* for vdRound, vmdround	
mode	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vm1SetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vsround, vmsround DOUBLE PRECISION for vdround, vmdround Fortran 90: REAL, INTENT(OUT) for vsround, vmsround DOUBLE PRECISION, INTENT(OUT) for vdround, vmdround C: float* for vsRound, vmsround double* for vdRound, vmdround	FORTRAN: Array that specifies the output vector y. C: Pointer to an array that contains the output vector y.

Description

The function computes a value rounded to the nearest integer for each vector element.

The resulting mode affects the results computed for inputs that fall half-way between consecutive integers.
For example:

- $f(0.5) = 0$, for rounding modes set to round to nearest round toward zero or to minus infinity.
- $f(0.5) = 1$, for rounding modes set to plus infinity.
- $f(-1.5) = -2$, for rounding modes set to round to nearest or to minus infinity.
- $f(-1.5) = -1$, for rounding modes set to round toward zero or to plus infinity.

Special Values for Real Function v?Round(x)

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?NearbyInt

Computes a rounded integer value in the current rounding mode for each vector element.

Syntax

Fortran:

```
call vsnearbyint( n, a, y )
call vmsnearbyint( n, a, y, mode )
call vdnearbyint( n, a, y )
call vmdnearbyint( n, a, y, mode )
```

C:

```
vsNearbyInt( n, a, y );
vmsNearbyInt( n, a, y, mode );
vdNearbyInt( n, a, y );
vmdNearbyInt( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsnearbyint, vmsnearbyint DOUBLE PRECISION for vdnearbyint, vmdnearbyint Fortran 90: REAL, INTENT(IN) for vsnearbyint, vmsnearbyint DOUBLE PRECISION, INTENT(IN) for vdnearbyint, vmdnearbyint C: const float* for vsNearbyInt, vmsNearbyInt const double* for vdNearbyInt, vmdNearbyInt	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN)	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Name	Type	Description
	C: const MKL_INT64	

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsnearbyint, vmsnearbyint DOUBLE PRECISION for vdnearbyint, vmdnearbyint	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .
	Fortran 90: REAL, INTENT(OUT) for vsnearbyint, vmsnearbyint DOUBLE PRECISION, INTENT(OUT) for vdnearbyint, vmdnearbyint	
	C: float* for vsNearbyInt, vmsnearbyint double* for vdNearbyInt, vmdnearbyint	

Description

The *v?NearbyInt* function computes a rounded integer value in a current rounding mode for each vector element.

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values.

Special Values for Real Function *v?NearbyInt(x)*

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Rint

Computes a rounded integer value in the current rounding mode for each vector element with inexact result exception raised for each changed value.

Syntax

Fortran:

```
call vsrint( n, a, y )
call vmsrint( n, a, y, mode )
call vdrint( n, a, y )
call vmdrint( n, a, y, mode )
```

C:

```
vsRint( n, a, y );
vmsRint( n, a, y, mode );
vdRint( n, a, y );
vmdRint( n, a, y, mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsrint, vmsrint DOUBLE PRECISION for vdrint, vmdrint Fortran 90: REAL, INTENT(IN) for vsrint, vmsrint DOUBLE PRECISION, INTENT(IN) for vdrint, vmdrint C: const float* for vsRint, vmsrint const double* for vdRint, vmdrint	FORTRAN: Array that specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER(KIND=8), INTENT(IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	FORTRAN 77: REAL for vsrint, vmsrint DOUBLE PRECISION for vdrint, vmdrint Fortran 90: REAL, INTENT(OUT) for vsrint, vmsrint	FORTRAN: Array that specifies the output vector <i>y</i> . C: Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description
	DOUBLE PRECISION, INTENT(OUT) for vdrint, vmdrint C: float* for vsRint, vmsrint double* for vdRint, vmdrint	

Description

The `v?Rint` function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The resulting mode affects the results computed for inputs that fall half-way between consecutive integers. For example:

- $f(0.5) = 0$, for rounding modes set to round to nearest round toward zero or to minus infinity.
- $f(0.5) = 1$, for rounding modes set to plus infinity.
- $f(-1.5) = -2$, for rounding modes set to round to nearest or to minus infinity.
- $f(-1.5) = -1$, for rounding modes set to round toward zero or to plus infinity.

Special Values for Real Function `v?Rint(x)`

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Modf

Computes a truncated integer value and the remaining fraction part for each vector element.

Syntax

Fortran:

```
call vsmodf( n, a, y, z )
call vmsmodf( n, a, y, z, mode )
call vdmodf( n, a, y, z )
call vmdmodf( n, a, y, z, mode )
```

C:

```
vsModf( n, a, y, z );
vmsModf( n, a, y, z, mode );
vdModf( n, a, y, z );
vmdModf( n, a, y, z, mode );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vml.f90`

- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vsmodf, vmsmodf DOUBLE PRECISION for vdmodf, vmdmodf Fortran 90: REAL, INTENT (IN) for vsmodf, vmsmodf DOUBLE PRECISION, INTENT (IN) for vdmodf, vmdmodf C: const float* for vsModf, vmsmodf const double* for vdModf, vmdmodf	FORTRAN: Array, specifies the input vector <i>a</i> . C: Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y, z</i>	FORTRAN 77: REAL for vsmodf, vmsmodf DOUBLE PRECISION for vdmodf, vmdmodf Fortran 90: REAL, INTENT (OUT) for vsmodf, vmsmodf DOUBLE PRECISION, INTENT (OUT) for vdmodf, vmdmodf C: float* for vsModf, vmsmodf double* for vdModf, vmdmodf	FORTRAN: Array, specifies the output vector <i>y</i> and <i>z</i> . C: Pointer to an array that contains the output vector <i>y</i> and <i>z</i> .

Description

The function computes a truncated integer value and the remaining fraction part for each vector element.

Halfway values, such as 0.5, -1.5, are rounded off towards even values. An inexact result exception is raised for each changed value.

Special Values for Real Function v?Modf(x)

Argument	Result 1	Result 2	Exception

VML Pack/Unpack Functions

This section describes VML functions that convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix B for details on vector indexing methods).

The table below lists available VML Pack/Unpack functions, together with data types and indexing methods associated with them.

VML Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
v?Pack	s, d, c, z	I, V, M	Gathers elements of arrays, indexed by different methods.
v?Unpack	s, d, c, z	I, V, M	Scatters vector elements to arrays with different indexing.

See Also

[Vector Arguments in VML](#)

v?Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax

Fortran:

```
call vspacki( n, a, inca, y )
call vspackv( n, a, ia, y )
call vspackm( n, a, ma, y )
call vdpacki( n, a, inca, y )
call vdpackv( n, a, ia, y )
call vdpackm( n, a, ma, y )
call vcpacki( n, a, inca, y )
call vcpackv( n, a, ia, y )
call vcpackm( n, a, ma, y )
call vzpacki( n, a, inca, y )
call vzpackv( n, a, ia, y )
call vzpackm( n, a, ma, y )
```

C:

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
vcPackI( n, a, inca, y );
vcPackV( n, a, ia, y );
vcPackM( n, a, ma, y );
vzPackI( n, a, inca, y );
vzPackV( n, a, ia, y );
vzPackM( n, a, ma, y );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the number of elements to be calculated.
<i>a</i>	FORTRAN 77: REAL for vspacki, vspackv, vspackm DOUBLE PRECISION for vdpacki, vdpackv, vdpackm COMPLEX for vcpacki, vcpackv, vcpackm DOUBLE COMPLEX for vzpacki, vzpackv, vzpackm Fortran 90: REAL, INTENT(IN) for vspacki, vspackv, vspackm DOUBLE PRECISION, INTENT(IN) for vdpacki, vdpackv, vdpackm COMPLEX, INTENT(IN) for vcpacki, vcpackv, vcpackm DOUBLE COMPLEX, INTENT(IN) for vzpacki, vzpackv, vzpackm	FORTRAN: Array, DIMENSION at least (1 + (n-1)*inca) for v?packi, Array, DIMENSION at least max(n,max(ia[j])), j=0, ..., n-1 for v?packv, Array, DIMENSION at least n for v?packm. C: Specifies pointer to an array that contains the input vector <i>a</i> . The arrays must be: for v?PackI, at least (1 + (n-1)*inca) for v?PackV, at least max(n,max(ia[j])), j=0, ..., n-1 for v?PackM, at least n.

Name	Type	Description
	C: const float* for vsPackI, vsPackV, vsPackM const double* for vdPackI, vdPackV, vdPackM const MKL_Complex8* for vcPackI, vcPackV, vcPackM const MKL_Complex16* for vzPackI, vzPackV, vzPackM	
inca	FORTRAN 77: INTEGER for vspacki, vdpacki, vcpacki, vzpacki Fortran 90: INTEGER, INTENT(IN) for vspacki, vdpacki, vcpacki, vzpacki C: const int for vsPackI, vdPackI, vcPackI, vzPackI	Specifies the increment for the elements of a .
ia	FORTRAN 77: INTEGER for vspackv, vdpackv, vcpackv, vzpackv Fortran 90: INTEGER, INTENT(IN) for vspackv, vdpackv, vcpackv, vzpackv C: const int* for vsPackV, vdPackV, vcPackV, vzPackV	FORTRAN: Array, DIMENSION at least n . Specifies the index vector for the elements of a . C: Specifies the pointer to an array of size at least n that contains the index vector for the elements of a .
ma	FORTRAN 77: INTEGER for vspackm, vdpackm, vcpackm, vzpackm Fortran 90: INTEGER, INTENT(IN) for vspackm, vdpackm, vcpackm, vzpackm C: const int* for vsPackM, vdPackM, vcPackM, vzPackM	FORTRAN: Array, DIMENSION at least n , Specifies the mask vector for the elements of a . C: Specifies the pointer to an array of size at least n that contains the mask vector for the elements of a .

Output Parameters

Name	Type	Description
y	FORTRAN 77: REAL for vspacki, vspackv, vspackm DOUBLE PRECISION for vdpacki, vdpackv, vdpackm COMPLEX for vcpacki, vcpackv, vcpackm	FORTRAN: Array, DIMENSION at least n . Specifies the output vector y . C: Pointer to an array of size at least n that contains the output vector y .

Name	Type	Description
	DOUBLE COMPLEX for vzpacki, vzpackv, vzpackm	
	Fortran 90: REAL, INTENT(OUT) for vspacki, vspackv, vspackm	
	DOUBLE PRECISION, INTENT(OUT) for vdpacki, vdpackv, vdpackm	
	COMPLEX, INTENT(OUT) for vcpacki, vcpackv, vcpackm	
	DOUBLE COMPLEX, INTENT(OUT) for vzpacki, vzpackv, vzpackm	
C:	float* for vsPackI, vsPackV, vsPackM	
	double* for vdPackI, vdPackV, vdPackM	
	const MKL_Complex8* for vcPackI, vcPackV, vcPackM	
	const MKL_Complex16* for vzPackI, vzPackV, vzPackM	

v?Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

Fortran:

```
call vsunpacki( n, a, y, incy )
call vsunpackv( n, a, y, iy )
call vsunpackm( n, a, y, my )
call vdunpacki( n, a, y, incy )
call vdunpackv( n, a, y, iy )
call vdunpackm( n, a, y, my )
call vcunpacki( n, a, y, incy )
call vcunpackv( n, a, y, iy )
call vcunpackm( n, a, y, my )
call vzunpacki( n, a, y, incy )
call vzunpackv( n, a, y, iy )
call vzunpackm( n, a, y, my )
```

C:

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
```

```
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
vcUnpackI( n, a, y, incy );
vcUnpackV( n, a, y, iy );
vcUnpackM( n, a, y, my );
vzUnpackI( n, a, y, incy );
vzUnpackV( n, a, y, iy );
vzUnpackM( n, a, y, my );
```

	const MKL_Complex16* for vzUnpackI, vzUnpackV, vzUnpackM	

VML Service Functions

The VML Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VML Service functions and their short description.

VML Service Functions

Function Short Name	Description
vmlSetMode	Sets the VML mode
vmlGetMode	Gets the VML mode
MKLFreeTls	Frees allocated VML/VSL thread local storage memory from within DllMain routine (Windows* OS only)
vmlSetErrStatus	Sets the VML Error Status
vmlGetErrStatus	Gets the VML Error Status
vmlClearErrStatus	Clears the VML Error Status
vmlSetErrorHandler	Sets the additional error handler callback function
vmlGetErrorHandler	Gets the additional error handler callback function
vmlClearErrorHandler	Deletes the additional error handler callback function

vmlSetMode

Sets a new mode for VML functions according to the mode parameter and stores the previous VML mode to oldmode.

Syntax

Fortran:

```
oldmode = vmlsetmode( mode )
```

C:

```
oldmode = vmlSetMode( mode );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>mode</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT (IN) C: const MKL_INT64	Specifies the VML mode to be set.

Output Parameters

Name	Type	Description
<i>oldmode</i>	FORTRAN: INTEGER*8 Fortran 90: INTEGER (KIND=8) C: MKL_INT64	Specifies the former VML mode.

Description

The `vmlSetMode` function sets a new mode for VML functions according to the `mode` parameter and stores the previous VML mode to `oldmode`. The mode change has a global effect on all the VML functions within a thread.

NOTE You can override the global mode setting and change the mode for a given VML function call by using a respective `vm[s,d]<Func>` variant of the function.

The `mode` parameter is designed to control accuracy, handling of denormalized numbers, and error handling. [Table "Values of the mode Parameter"](#) lists values of the `mode` parameter. You can obtain all other possible values of the `mode` parameter values by using bitwise OR (|) operation to combine one value for accuracy, one value for handling of denormalized numbers, and one value for error control options. The default value of the `mode` parameter is `VML_HA | VML_FTZDAZ_OFF | VML_ERRMODE_DEFAULT`.

The `VML_FTZDAZ_ON` mode is specifically designed to improve the performance of computations that involve denormalized numbers at the cost of reasonable accuracy loss. This mode changes the numeric behavior of the functions: denormalized input values are treated as zeros (`DAZ` = denormals-are-zero) and denormalized results are flushed to zero (`FTZ` = flush-to-zero). Accuracy loss may occur if input and/or output values are close to denormal range.

Values of the mode Parameter

Value of mode	Description
Accuracy Control	
<code>VML_HA</code>	high accuracy versions of VML functions
<code>VML_LA</code>	low accuracy versions of VML functions
<code>VML_EP</code>	enhanced performance accuracy versions of VML functions
Denormalized Numbers Handling Control	

Value of mode	Description
VML_FTZDAZ_ON	Faster processing of denormalized inputs is enabled.
VML_FTZDAZ_OFF	Faster processing of denormalized inputs is disabled.
Error Mode Control	
VML_ERRMODE_IGNORE	No action is set for computation errors.
VML_ERRMODE_ERRNO	On error, the <code>errno</code> variable is set.
VML_ERRMODE_STDERR	On error, the error text information is written to <code>stderr</code> .
VML_ERRMODE_EXCEPT	On error, an exception is raised.
VML_ERRMODE_CALLBACK	On error, an additional error handler function is called.
VML_ERRMODE_DEFAULT	On error, the <code>errno</code> variable is set, an exception is raised, and an additional error handler function is called.

Examples

The following example shows how to set low accuracy, fast processing for denormalized numbers and `errno` error mode in the Fortran and C languages:

```
oldmode = vmlsetmode( VML_LA )
call vmlsetmode( IOR(VML_LA, VML_FTZDAZ_ON, VML_ERRMODE_ERRNO) )

vmlSetMode( VML_LA );
vmlSetMode( VML_LA | VML_FTZDAZ_ON | VML_ERRMODE_ERRNO );
```

vmlGetMode

Gets the VML mode.

Syntax

Fortran:

```
mod = vmlgetmode()
```

C:

```
mod = vmlGetMode( void );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vml.f90`
- C: `mkl.h`

Output Parameters

Name	Type	Description
<i>mod</i>	FORTRAN: INTEGER C: int	Specifies the packed <i>mode</i> parameter.

Description

The function `vmlGetMode()` returns the VML *mode* parameter that controls accuracy, handling of denormalized numbers, and error handling options. The *mod* variable value is a combination of the values listed in the table "[Values of the *mode* Parameter](#)". You can obtain these values using the respective mask from the table "[Values of Mask for the *mode* Parameter](#)".

Values of Mask for the `mode` Parameter

Value of mask	Description
<code>VML_ACCURACY_MASK</code>	Specifies mask for accuracy <code>mode</code> selection.
<code>VML_FTZDAZ_MASK</code>	Specifies mask for FTZDAZ <code>mode</code> selection.
<code>VML_ERRMODE_MASK</code>	Specifies mask for error <code>mode</code> selection.

See example below:

Examples

```
mod = vmlgetmode()

accm = IAND(mod, VML_ACCURACY_MASK)

denm = IAND(mod, VML_FTZDAZ_MASK)

errm = IAND(mod, VML_ERRMODE_MASK)

accm = vmlGetMode(void) & VML_ACCURACY_MASK;
denm = vmlGetMode(void) & VML_FTZDAZ_MASK;
errm = vmlGetMode(void) & VML_ERRMODE_MASK;
```

MKLFreeTls

Frees allocated VML/VSL thread local storage memory from within DllMain routine. Use on Windows OS only.*

Syntax

C:

```
void MKLFreeTLS( const MKL_UINT fdwReason );
```

Include Files

- C: mkl_vml_functions_win.h

Description

The `MKLFreeTLS` routine frees thread local storage (TLS) memory which has been allocated when using MKL static libraries to link into a DLL on the Windows* OS. The routine should only be used within `DllMain`.

NOTE It is only necessary to use `MKLFreeTLS` for TLS data in the VML and VSL domains.

Input Parameters

Name	Type	Description
<code>fdwReason</code>	const MKL_UINT	Reason code from the <code>DllMain</code> call.

Example

```
BOOL WINAPI DllMain(HINSTANCE hInst, DWORD fdwReason, LPVOID lpvReserved)
{
    /*customer code*/
    MKLFreeTLS(fdwReason);
    /*customer code*/
}
```

vmlSetErrStatus

Sets the new VML Error Status according to *err* and stores the previous VML Error Status to *olderr*.

Syntax

Fortran:

```
olderr = vmlseterrstatus( err )
```

C:

```
olderr = vmlSetErrStatus( err );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>err</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Specifies the VML error status to be set.

Output Parameters

Name	Type	Description
<i>olderr</i>	FORTRAN: INTEGER C: int	Specifies the former VML error status.

Description

Table "Values of the VML Status" lists possible values of the *err* parameter.

Values of the VML Status

Status	Description
Successful Execution	
VML_STATUS_OK	The execution was completed successfully.
Warnings	
VML_STATUS_ACCURACYWARNING	The execution was completed successfully in a different accuracy mode.
Errors	
VML_STATUS_BADSIZE	The function does not support the preset accuracy mode. The Low Accuracy mode is used instead.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.

Status	Description
VML_STATUS_SING	At least one of the input array values causes a divide-by-zero exception or produces an invalid (QNaN) result.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
olderr = vmlSetErrStatus( VML_STATUS_OK );
olderr = vmlSetErrStatus( VML_STATUS_ERRDOM );
olderr = vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

vmlGetErrStatus

Gets the VML Error Status.

Syntax

Fortran:

```
err = vmlgeterrstatus( )
```

C:

```
err = vmlGetErrStatus( void );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Type	Description
err	FORTRAN: INTEGER C: int	Specifies the VML error status.

vmlClearErrStatus

Sets the VML Error Status to VML_STATUS_OK and stores the previous VML Error Status to olderr.

Syntax

Fortran:

```
olderr = vmlclearerrstatus( )
```

C:

```
olderr = vmlClearErrStatus( void );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vml.f90

- C: mkl.h

Output Parameters

Name	Type	Description
olderr	FORTRAN: INTEGER C: int	Specifies the former VML error status.

vmlSetErrorCallBack

Sets the additional error handler callback function and gets the old callback function.

Syntax

Fortran:

```
oldcallback = vmlseterrorcallback( callback )
```

C:

```
oldcallback = vmlSetErrorCallBack( callback );
```

Include Files

- Fortran 90: mkl_vml.f90
- C: mkl.h

Input Parameters

Name	Description
FORTRAN: Address of the callback function. <i>callback</i>	The callback function has the following format: <pre>INTEGER FUNCTION ERRFUNC(par) TYPE (ERROR_STRUCTURE) par ! ... ! user error processing ! ... ERRFUNC = 0 ! if ERRFUNC= 0 - standard VML error handler ! is called after the callback ! if ERRFUNC != 0 - standard VML error handler ! is not called END</pre>

Name**Description**

The passed error structure is defined as follows:

```
TYPE ERROR_STRUCTURE SEQUENCE
```

```
INTEGER*4 ICODE
```

```
INTEGER*4 IIINDEX
```

```
REAL*8 DBA1
```

```
REAL*8 DBA2
```

```
REAL*8 DBR1
```

```
REAL*8 DBR2
```

```
CHARACTER(64) CFUNCNAME
```

```
INTEGER*4 IFUNCNAMELEN
```

```
REAL*8 DBA1IM
```

```
REAL*8 DBA2IM
```

```
REAL*8 DBR1IM
```

```
REAL*8 DBR2IM
```

```
END TYPE ERROR_STRUCTURE
```

C: *callback* Pointer to the callback function.

The callback function has the following format:

```
static int __stdcall
```

```
MyHandler(DefVmlErrorContext*
```

```
pContext)
```

```
{
```

```
/* Handler body */
```

```
};
```

Name**Description**

The passed error structure is defined as follows:

```
typedef struct _DefVmlErrorContext
{
    int iCode; /* Error status value */
    int iIndex; /* Index for bad array
                  element, or bad array
                  dimension, or bad
                  array pointer */

    double dbA1; /* Error argument 1 */
    double dbA2; /* Error argument 2 */
    double dbR1; /* Error result 1 */
    double dbR2; /* Error result 2 */
    char cFuncName[64]; /* Function name */
    int iFuncNameLen; /* Length of functionname*/
    double dbA1Im; /* Error argument 1, imag part*/
    double dbA2Im; /* Error argument 2, imag part*/
    double dbR1Im; /* Error result 1, imag part*/
    double dbR2Im; /* Error result 2, imag part*/
} DefVmlErrorContext;
```

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER C: int	FORTRAN: Address of the former callback function. C: Pointer to the former callback function.

NOTE This function does not have a FORTRAN 77 interface due to the use of internal structures.

Description

The callback function is called on each VML mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see "[Values of the `mode` Parameter](#)").

Use the `vmlSetErrorHandler()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns 0.

vmlGetErrorCallBack

Gets the additional error handler callback function.

Syntax

Fortran:

```
callback = vmlgeterrorcallback( )
```

C:

```
callback = vmlGetErrorCallBack( void );
```

Include Files

- Fortran 90: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Description
<i>callback</i>	Fortran 90: Address of the callback function C: Pointer to the callback function

vmlClearErrorCallBack

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

Fortran:

```
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldcallback = vmlClearErrorCallBack( void );
```

Include Files

- Fortran 90: mkl_vml.f90
- C: mkl.h

Output Parameters

Name	Type	Description
<i>oldcallback</i>	Fortran 90: INTEGER C: int	FORTRAN: Address of the former callback function C: Pointer to the former callback function

Statistical Functions

Statistical functions in Intel® MKL are known as Vector Statistical Library (VSL) that is designed for the purpose of

- generating vectors of pseudorandom, quasi-random, and deterministic random numbers
- performing mathematical operations of convolution and correlation
- computing basic statistical estimates for single and double precision multi-dimensional datasets

The corresponding functionality is described in the respective [Random Number Generators](#), [Convolution and Correlation](#), and [VSL Summary Statistics](#) sections.

See VSL performance data in the online VSL Performance Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

The basic notion in VSL is a task. The task object is a data structure or descriptor that holds the parameters related to a specific statistical operation: random number generation, convolution and correlation, or summary statistics estimation. Such parameters can be an identifier of a random number generator, its internal state and parameters, data arrays, their shape and dimensions, an identifier of the operation and so forth. You can modify the VSL task parameters using the respective service functionality of the library.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Random Number Generators

Intel MKL VSL provides a set of routines implementing commonly used pseudorandom, quasi-random, or non-deterministic random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and the library of vector mathematical functions (VML, see [Chapter 9, "Vector Mathematical Functions"](#)).

VSL provides interfaces both for Fortran and C languages. For users of the C and C++ languages the `mkl_vsl.h` header file is provided. For users of the Fortran 90 or Fortran 95 language the `mkl_vsl.f90` header file is provided. The `mkl_vsl.fi` header file available in the previous versions of Intel MKL is retained for backward compatibility. For users of the FORTRAN 77 language the `mkl_vsl.f77` header file is provided. All header files are found in the following directory:

```
 ${MKL}/include
```

The `mkl_vsl.f90` header is intended for use with the Fortran `include` clause and is compatible with both standard forms of F90/F95 sources - the free and 72-columns fixed forms. If you need to use the VSL interface with 80- or 132-columns fixed form sources, you may add a new file to your project. That file is formatted as a 72-columns fixed-form source and consists of a single `include` clause as follows:

```
include 'mkl_vsl.f90'
```

This `include` clause causes the compiler to generate the module files `mkl_vsl.mod` and `mkl_vsl_type.mod`, which are used to process the Fortran use clauses referencing to the VSL interface:

```
use mkl_vsl_type
use mkl_vsl
```

Because of this specific feature, you do not need to include the `mkl_vsl.f90` header into each source of your project. You only need to include the header into some of the sources. In any case, make sure that the sources that depend on the VSL interface are compiled after those that include the header so that the module files `mkl_vsl.mod` and `mkl_vsl_type.mod` are generated prior to using them.

The `mkl_vsl.f77` header is intended for use with the Fortran `include` clause as follows:

```
include 'mkl_vsl.f77'
```

NOTE For Fortran 90 interface, VSL provides both subroutine-style interface and function-style interface. Default interface in this case is a function-style interface. Function-style interface, unlike subroutine-style interface, allows the user to get error status of each routine. Subroutine-style interface is provided for backward compatibility only. To use subroutine-style interface, manually include `mkl_vsl_subroutine.fi` file instead of `mkl_vsl.f90` by changing the line `include 'mkl_vsl.f90'` in `include\mkl.fi` with the line `include 'mkl_vsl_subroutine.fi'`.

For the FORTRAN 77 interface, VSL provides only function-style interface.

All VSL routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are pseudorandom, quasi-random, or non-deterministic random number generators. Detailed description of the generators can be found in [Distribution Generators](#) section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Routines](#) section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Routines](#) section).

The last two categories are referred to as service routines.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to the '*Random Numbers*' section in [VSL Notes](#) document provided at the Intel® MKL web page.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VSL Notes](#) for the description of methods available for each generator.

An RNG task determines environment in which random number generation is performed, in particular parameters of the BRNG and its internal state. Output of VSL generators is a stream of random numbers that are used in Monte Carlo simulations. A *random stream descriptor* and a *random stream* are used as synonyms of an *RNG task* in the document unless the context requires otherwise.

The *random stream descriptor* specifies which BRNG should be used in a given transformation method. See the *Random Streams and RNGs in Parallel Computation* section of [VSL Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \dots\}$.
Z	The set of integers $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$.
R	The set of real numbers.
$\lfloor a \rfloor$	The floor of a (the largest integer less than or equal to a).
\oplus or xor	Bitwise exclusive OR.
C_{α}^{κ} or $\binom{\alpha}{\kappa}$	Binomial coefficient or combination ($\alpha \in R$, $\alpha \geq 0$; $\kappa \in N \cup \{0\}$).
$C_{\alpha}^0 = 1$	
	For $\alpha \geq k$ binomial coefficient is defined as
	$C_{\alpha}^{\kappa} = \frac{\alpha(\alpha - 1) \dots (\alpha - \kappa + 1)}{\kappa!}$
	If $\alpha < k$, then
	$C_{\alpha}^{\kappa} = 0$
$\Phi(x)$	Cumulative Gaussian distribution function
	$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$
	defined over $-\infty < x < +\infty$.
	$\Phi(-\infty) = 0$, $\Phi(+\infty) = 1$.
$\Gamma(\alpha)$	The complete gamma function
	$\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1} e^{-t} dt$
	where $\alpha > 0$.
$B(p, q)$	The complete beta function

$$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$$

where $p > 0$ and $q > 0$.

$\text{LCG}(a, c, m)$

Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where a is called the *multiplier*, c is called the *increment*, and m is called the *modulus* of the generator.

$\text{MCG}(a, m)$

Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment c is taken to be 0.

$\text{GFSR}(p, q)$

Generalized Feedback Shift Register Generator

$$x_n = x_{n-p} \oplus x_{n-q}.$$

Naming Conventions

The names of the Fortran routines in VSL random number generators are lowercase (`virnguniform`). The names are not case-sensitive.

In C, the names of the routines, types, and constants are case-sensitive and can be lowercase and uppercase (`viRngUniform`).

The names of generator routines have the following structure:

`v<type of result>rng<distribution>` for the Fortran interface

`v<type of result>Rng<distribution>` for the C interface,

where

- `v` is the prefix of a VSL vector function.
- `<type of result>` is either `s`, `d`, or `i` and specifies one of the following types:

<code>s</code>	REAL for the Fortran interface float for the C interface
<code>d</code>	DOUBLE PRECISION for the Fortran interface double for the C interface
<code>i</code>	INTEGER for the Fortran interface int for the C interface Prefixes <code>s</code> and <code>d</code> apply to continuous distributions only, prefix <code>i</code> applies only to discrete case.
- `rng` indicates that the routine is a random generator.
- `<distribution>` specifies the type of statistical distribution.

Names of service routines follow the template below:

`vsl<name>`

where

- `vsl` is the prefix of a VSL service function.
- `<name>` contains a short function name.

For a more detailed description of service routines, refer to [Service Routines](#) and [Advanced Service Routines](#) sections.

Prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>(<method, stream, n, r, [<distribution parameters>] )
```

where

- *method* defines the method of generation. A detailed description of this parameter can be found in table "Values of <*method*> in *method* parameter". See the next page, where the structure of the *method* parameter name is explained.
- *stream* defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- *n* defines the number of random values to be generated. If *n* is less than or equal to zero, no values are generated. Furthermore, if *n* is negative, an error condition is set.
- *r* defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least *n* random numbers.
- *status* defines the error status of a VSL routine. See [Error Reporting](#) section for a detailed description of error status values.

Additional parameters included into *<distribution parameters>* field are individual for each generator routine and are described in detail in [Distribution Generators](#) section.

To invoke a distribution generator, use a call to the respective VSL routine. For example, to obtain a vector *r*, composed of *n* independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value *a* and standard deviation *sigma*, write the following:

for the Fortran interface

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

for the C interface

```
status = vsRngGaussian( method, stream, n, r, a, sigma )
```

The name of a *method* parameter has the following structure:

```
VSL_RNG_METHOD_<method>_<distribution>
```

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

where

- *<distribution>* is the probability distribution.
- *<method>* is the method name.

Type of the name structure for the *method* parameter corresponds to fast and accurate modes of random number generation (see "[Distribution Generators](#)" section and [VSL Notes](#) for details).

Method names `VSL_RNG_METHOD_<distribution>_<method>`

and

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

should be used with

```
v<precision>Rng<distribution>
```

function only, where

- *<precision>* is
 - s* for single precision continuous distribution
 - d* for double precision continuous distribution
 - i* for discrete distribution
- *<distribution>* is the probability distribution.

is the probability distribution. [Table "Values of <method> in *method* parameter"](#) provides specific predefined values of the *method* name. The third column contains names of the functions that use the given method.

[Values of <method> in *method* parameter](#)

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous), Uniform

Method	Short Description	Functions
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula:	(discrete), UniformBits , UniformBits32 , UniformBits64
	$x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian , GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas:	Gaussian , GaussianMV , Lognormal
	$x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	
	$x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	
ICDF	Inverse cumulative distribution function method.	Exponential , Laplace , Weibull , Cauchy , Rayleigh , Gumbel , Bernoulli , Geometric , Gaussian , GaussianMV
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	Gamma
CJA	For $\min(p, q) > 1$, Cheng method is used; for $\min(p, q) < 1$, Johnk method is used, if $q + K \cdot p^2 + C \leq 0$ ($K = 0.852\dots$, $C = -0.956\dots$) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$, method of Johnk is used; for $\min(p, q) < 1$, $\max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $n_{trial} \cdot \min(p, 1 - p) \geq 30$ with decomposition into 4 regions:	Binomial

Method	Short Description	Functions
	<ul style="list-style-type: none"> - 2 parallelograms - triangle - left exponential tail - right exponential tail 	
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: <ul style="list-style-type: none"> - rectangular - left exponential tail - right exponential tail 	Hypergeometric
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: <ul style="list-style-type: none"> - 2 parallelograms - triangle - left exponential tail - right exponential tail; <p>otherwise, table lookup method is used.</p>	Poisson
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	Poisson , PoissonV
NBAR	Acceptance/rejection method for ,	NegBinomial
	$\frac{(a - 1) \cdot (1 - p)}{p} \geq 100$	
	with decomposition into 5 regions: <ul style="list-style-type: none"> - rectangular - 2 trapezoid - left exponential tail - right exponential tail 	

NOTE In this document, routines are often referred to by their base name (Gaussian) when this does not lead to ambiguity. In the routine reference, the full name (`vsrnggaussian`, `vsRngGaussian`) is always used in prototypes and code examples.

Basic Generators

VSL provides pseudorandom, quasi-random, and non-deterministic random number generators. This includes the following BRNGs, which differ in speed and other properties:

- the 31-bit multiplicative congruential pseudorandom number generator $MCG(1132489760, 2^{31} - 1)$ [[L'Ecuyer99](#)]
- the 32-bit generalized feedback shift register pseudorandom number generator $GFSR(250, 103)$ [[Kirkpatrick81](#)]
- the combined multiple recursive pseudorandom number generator $MRG32k3a$ [[L'Ecuyer99a](#)]

- the 59-bit multiplicative congruential pseudorandom number generator $MCG(13^{13}, 2^{59})$ from NAG Numerical Libraries [NAG]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [NAG]
- Mersenne Twister pseudorandom number generator $MT19937$ [Matsumoto98] with period length $2^{19937}-1$ of the produced sequence
- Set of 6024 Mersenne Twister pseudorandom number generators $MT2203$ [Matsumoto98], [Matsumoto00]. Each of them generates a sequence of period length equal to $2^{2203}-1$. Parameters of the generators provide mutual independence of the corresponding sequences.
- SIMD-oriented Fast Mersenne Twister pseudorandom number generator $SFMT19937$ [Saito08] with a period length equal to $2^{19937}-1$ of the produced sequence.
- Sobol quasi-random number generator [Sobol76], [Bratley88], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).
- Niederreiter quasi-random number generator [Bratley92], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VSL Notes](#).
- Non-deterministic random number generator (RDRAND-based generators only) [AVX], [[IntelSWMan](#)].

NOTE You can use a non-deterministic random number generator only if the underlying hardware supports it. For instructions on how to detect if an Intel CPU supports a non-deterministic random number generator see, for example, *Chapter 8: Post-32nm Processor Instructions* in [AVX] or *Chapter 4: RdRand Instruction Usage* in [BMT].

NOTE The time required by some non-deterministic sources to generate a random number is not constant, so you might have to make multiple requests before the next random number is available. VSL limits the number of retries for requests to the non-deterministic source to 10. You can redefine the maximum number of retries during the initialization of the non-deterministic random number generator with the `vslNewStreamEx` function.

For more details on the non-deterministic source implementation for Intel CPUs please refer to Section 7.3.17, Volume 1, *Random Number Generator Instruction* in [[IntelSWMan](#)] and Section 4.2.2, *RdRand Retry Loop* in [BMT].

See some testing results for the generators in [VSL Notes](#) and comparative performance data at http://software.intel.com/sites/products/documentation/hpc/mkl/vsl/vsl_data/vsl_performance_data.htm.

VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

For some basic generators, VSL provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VSL provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

There is also an option to utilize externally generated random numbers in VSL distribution generator routines. For this purpose VSL provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (a, b) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (a, b) interval.

Such basic generators are called the abstract basic random number generators.

See [VSL Notes](#) for a more detailed description of the generator properties.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MR32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 6024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SFMT19937	A SIMD-oriented Fast Mersenne Twister pseudorandom number generator.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$; user-defined dimensions are also available.
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.
VSL_BRNG_NONDETERM	A non-deterministic random number generator.

See [VSL Notes](#) for detailed description.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. You can operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VSL Notes](#) for details.

NOTE Random streams associated with abstract basic random number generator are called the abstract random streams. See [VSL Notes](#) for detailed description of abstract streams and their use.

You can create unlimited number of random streams by VSL [Service Routines](#) like `NewStream` and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine `DeleteStream`.

VSL provides service functions `SaveStreamF` and `LoadStreamF` to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VSL Notes](#) for detailed description.

Data Types

FORTRAN 77:

```
INTEGER*4 vslstreamstate(2)
```

Fortran 90:

```
TYPE
    VSL_STREAM_STATE
INTEGER*4 descriptor1
INTEGER*4 descriptor2
END
    TYPE VSL_STREAM_STATE
```

C:

```
typedef (void*) VSLStreamStatePtr;
```

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

Error Reporting

VSL RNG routines return status codes of the performed operation to report errors to the calling program. The application should perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

`VSL_ERROR_<ERROR_NAME>` - indicates VSL errors common for all VSL domains.

`VSL_RNG_ERROR_<ERROR_NAME>` - indicates VSL RNG errors.

VSL RNG errors are of negative values while warnings are of positive values. The status code of zero value indicates successful completion of the operation: `VSL_ERROR_OK` (or synonymous `VSL_STATUS_OK`).

Status Codes

Status Code	Description
Common VSL	
VSL_ERROR_OK, VSL_STATUS_OK	No error, execution is successful.
VSL_ERROR_BADARGS	Input argument value is not valid.
VSL_ERROR_CPU_NOT_SUPPORTED	CPU version is not supported.
VSL_ERROR_FEATURE_NOT_IMPLEMENTED	Feature invoked is not implemented.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory.
VSL_ERROR_NULL_PTR	Input pointer argument is NULL.
VSL_ERROR_UNKNOWN	Unknown error.
VSL RNG Specific	
VSL_RNG_ERROR_BAD_FILE_FORMAT	File format is unknown.
VSL_RNG_ERROR_BAD_MEM_FORMAT	Descriptive random stream format is unknown.
VSL_RNG_ERROR_BAD_NBITS	The value in NBits field is bad.
VSL_RNG_ERROR_BAD_NSEEDS	The value in NSeeds field is bad.
VSL_RNG_ERROR_BAD_STREAM	The random stream is invalid.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	The value in StreamStateSize field is bad.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_RNG_ERROR_BAD_WORD_SIZE	The value in WordSize field is bad.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_RNG_ERROR_FILE_CLOSE	Error in closing the file.
VSL_RNG_ERROR_FILE_OPEN	Error in opening the file.
VSL_RNG_ERROR_FILE_READ	Error in reading the file.
VSL_RNG_ERROR_FILE_WRITE	Error in writing the file.
VSL_RNG_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

Status Code	Description
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator is exceeded.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_RNG_ERROR_NONDETERM_NOT_SUPPORTED	Non-deterministic random number generator is not supported on the CPU running the application.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number using non-deterministic random number generator exceeds threshold (see Section 7.2.1.12 <i>Non-deterministic</i> in [VSL Notes] for more details)

VSL RNG Usage Model

A typical algorithm for VSL random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream/streams. Function `vslDeleteStream`.

NOTE You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following C example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters $a = 5$ and $\sigma = 2$. Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

C Example of VSL RNG Usage

```
#include <stdio.h>
#include "mkl_vsl.h"

int main()
{
    double r[1000]; /* buffer for random numbers */
    double s; /* average */
    VSLStreamStatePtr stream;
    int i, j;

    /* Initializing */
    s = 0.0;
    vslNewStream( &stream, VSL_BRNG_MT19937, 777 );

    /* Generating */
    for ( i=0; i<10; i++ );
    {
        vdRngGaussian( VSL_RNG_METHOD_GAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0 );
        for ( j=0; j<1000; j++ );
        {
            s += r[j];
        }
    }
}
```

```

        }
    }
    s /= 10000.0;

    /* Deleting the stream */
    vslDeleteStream( &stream );

    /* Printing results */
    printf( "Sample mean of normal distribution = %f\n", s );

    return 0;
}

```

The Fortran version of the same example is below:

Fortran Example of VSL RNG Usage

```

include 'mkl_vsl.f90'

program MKL_VSL_GAUSSIAN

USE MKL_VSL_TYPE
USE MKL_VSL

real(kind=8) r(1000) ! buffer for random numbers
real(kind=8) s         ! average
real(kind=8) a, sigma ! parameters of normal distribution

TYPE (VSL_STREAM_STATE) :: stream

integer(kind=4) errcode
integer(kind=4) i,j
integer brng,method,seed,n

n = 1000
s = 0.0
a = 5.0
sigma = 2.0
brng=VSL_BRNG_MT19937
method=VSL_RNG_METHOD_GAUSSIAN_ICDF
seed=777

! ***** Initializing *****
errcode=vslnewstream( stream, brng, seed )

! ***** Generating *****
do i = 1,10
    errcode=vdrnggaussian( method, stream, n, r, a, sigma )
    do j = 1, 1000
        s = s + r(j)
    end do
end do

s = s / 10000.0

! ***** Deinitialize *****
errcode=vsldeletestream( stream )

! ***** Printing results *****
print *, "Sample mean of normal distribution = ", s

end

```

Additionally, examples that demonstrate usage of VSL random number generators are available in the following directories:

`${MKL}/examples/vslc/source`

`${MKL}/examples/vslf/source`

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. [Table "Service Routines"](#) lists all available service routines

Service Routines

Routine	Short Description
<code>vslNewStream</code>	Creates and initializes a random stream.
<code>vslNewStreamEx</code>	Creates and initializes a random stream for the generators with multiple initial conditions.
<code>vsliNewAbstractStream</code>	Creates and initializes an abstract random stream for integer arrays.
<code>vsldNewAbstractStream</code>	Creates and initializes an abstract random stream for double precision floating-point arrays.
<code>vslsNewAbstractStream</code>	Creates and initializes an abstract random stream for single precision floating-point arrays.
<code>vslDeleteStream</code>	Deletes previously created stream.
<code>vslCopyStream</code>	Copies a stream to another stream.
<code>vslCopyStreamState</code>	Creates a copy of a random stream state.
<code>vslSaveStreamF</code>	Writes a stream to a binary file.
<code>vslLoadStreamF</code>	Reads a stream from a binary file.
<code>vslSaveStreamM</code>	Writes a random stream descriptive data, including state, to a memory buffer.
<code>vslLoadStreamM</code>	Creates a new stream and reads stream descriptive data, including state, from the memory buffer.
<code>vslGetStreamSize</code>	Computes size of memory necessary to hold the random stream.
<code>vslLeapfrogStream</code>	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
<code>vslSkipAheadStream</code>	Initializes the stream by the skip-ahead method.
<code>vslGetStreamStateBrng</code>	Obtains the index of the basic generator responsible for the generation of a given random stream.
<code>vslGetNumRegBrngs</code>	Obtains the number of currently registered basic generators.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream (`vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream (`vslDeleteStream`).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the `vslDeleteStream` function to delete all the streams afterwards.

vslNewStream

Creates and initializes a random stream.

Syntax

Fortran:

```
status = vslnewstream( stream, brng, seed )
```

C:

```
status = vslNewStream( &stream, brng, seed );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
brng	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Index of the basic generator to initialize the stream. See Table Values of brng parameter for specific value.
seed	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const unsigned int	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that brng can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
stream	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Stream state descriptor

Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. See [VSL Notes](#) for a more detailed description of stream initialization for different basic generators.

NOTE This function is not applicable for abstract basic random number generators. Please use [vslsNewAbstractStream](#), [vslsNewAbstractStream](#) or [vslsNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPP	Non-deterministic random number generator is not supported.

vslNewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

Fortran:

```
status = vslnewstreamex( stream, brng, n, params )
```

C:

```
status = vslNewStreamEx( &stream, brng, n, params );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>brng</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Index of the basic generator to initialize the stream. See Table "Values of <i>brng</i> parameter" for specific value.
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of initial conditions contained in <i>params</i>
<i>params</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const unsigned int	Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Stream state descriptor

Name	Type	Description
Fortran 90:		

TYPE(VSL_STREAM_STATE),
INTENT(OUT)

C: VSLStreamStatePtr*

Description

The `vslNewStreamEx` function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator `brng`. Whenever possible, use `vslNewStream`, which is analogous to `vslNewStreamEx` except that it takes only one 32-bit initial condition. In particular, `vslNewStreamEx` may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VSL Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VSL Notes](#) for the format for their passing and registration in VSL.

NOTE This function is not applicable for abstract basic random number generators. Please use `vsliNewAbstractStream`, `vslsNewAbstractStream` or `vsldNewAbstractStream` to utilize integer, single-precision or double-precision external random data respectively.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_RNG_ERROR_INVALID_BRNG_INDEX</code>	BRNG index is invalid.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <code>stream</code> .
<code>VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPP</code>	Non-deterministic random number generator is not supported.

[vsliNewAbstractStream](#)

Creates and initializes an abstract random stream for integer arrays.

Syntax

Fortran:

```
status = vslineawbstractstream( stream, n, ibuf, icallback )
```

C:

```
status = vsliNewAbstractStream( &stream, n, ibuf, icallback );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>n</code>	FORTRAN 77: INTEGER	Size of the array <code>ibuf</code>

Name	Type	Description
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
<i>ibuf</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER(KIND=4), INTENT (IN)	Array of <i>n</i> 32-bit integers
	C: const unsigned int	
<i>icallback</i>	See Note below	Fortran: Address of the callback function used for <i>ibuf</i> update C: Pointer to the callback function used for <i>ibuf</i> update

NOTE Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION IUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
INTEGER*4 ibuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION IUPDATEFUNC[C]( stream, n, ibuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN)    :: n[reference]
INTEGER(KIND=4),INTENT(OUT)   :: ibuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)    :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)    :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)    :: idx[reference]
```

Format of the callback function in C:

```
int iUpdateFunc( VSLStreamStatePtr stream, int* n, unsigned int ibuf[], int* nmin, int* nmax,
int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table icallback Callback Function Parameters](#) gives the description of the callback function parameters.

[icallback Callback Function Parameters](#)

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>ibuf</i>
<i>ibuf</i>	Array of random numbers associated with the stream <i>stream</i>

Parameters	Short Description
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$.

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), TINTENT(OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

Description

The `vsliNewAbstractStream` function creates a new abstract stream and associates it with an integer array *ibuf* and your callback function *icallback* that is intended for updating of *ibuf* content.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BADARGS</code>	Parameter <i>n</i> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <i>stream</i> .
<code>VSL_ERROR_NULL_PTR</code>	Either buffer or callback function parameter is a NULL pointer.

`vsldNewAbstractStream`

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

Fortran:

```
status = vsldnewabstractstream( stream, n, dbuf, a, b, dcallback )
```

C:

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Size of the array <i>dbuf</i>
<i>dbuf</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL (KIND=8), INTENT (IN) C: const double	Array of <i>n</i> double precision floating-point random numbers with uniform distribution over interval (<i>a,b</i>)
<i>a</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL (KIND=8), INTENT (IN) C: const double	Left boundary <i>a</i>
<i>b</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL (KIND=8), INTENT (IN) C: const double	Right boundary <i>b</i>
<i>dcallback</i>	See Note below	Fortran: Address of the callback function used for update of the array <i>dbuf</i> C: Pointer to the callback function used for update of the array <i>dbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure

**NOTE Format of the callback function in FORTRAN 77:**

```
INTEGER FUNCTION DUPDATEFUNC( stream, n, dbuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
DOUBLE PRECISION dbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION DUPDATEFUNC[C]( stream, n, dbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN) :: n[reference]
REAL(KIND=8),INTENT(OUT) :: dbuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN) :: nmin[reference]
INTEGER(KIND=4),INTENT(IN) :: nmax[reference]
INTEGER(KIND=4),INTENT(IN) :: idx[reference]
```

Format of the callback function in C:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int* nmax, int*
idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table dcallback Callback Function Parameters](#) gives the description of the callback function parameters.

[dcallback Callback Function Parameters](#)

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>dbuf</i>
<i>dbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$.

Description

The `vslNewAbstractStream` function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a double precision array *dbuf* and your callback function *dcallback* that is intended for updating of *dbuf* content.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BADARGS</code>	Parameter <i>n</i> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <i>stream</i> .

VSL_ERROR_NULL_PTR

Either buffer or callback function parameter is a NULL pointer.

vslsNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

Fortran:

```
status = vslsnewabstractstream( stream, n, sbuf, a, b, scallback )
```

C:

```
status = vslsNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Size of the array <i>sbuf</i>
<i>sbuf</i>	FORTRAN 77: REAL Fortran 90: REAL(KIND=4), INTENT(IN) C: const float	Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (<i>a,b</i>)
<i>a</i>	FORTRAN 77: REAL Fortran 90: REAL(KIND=4), INTENT(IN) C: const float	Left boundary <i>a</i>
<i>b</i>	FORTRAN 77: REAL Fortran 90: REAL(KIND=4), INTENT(IN) C: const float	Right boundary <i>b</i>
<i>scallback</i>	See Note below	Fortran: Address of the callback function used for update of the array <i>sbuf</i> C: Pointer to the callback function used for update of the array <i>sbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Descriptor of the stream state structure stream(2)

NOTE Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION SUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
REAL sbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION SUPDATEFUNC[C]( stream, n, sbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN) :: n[reference]
REAL(KIND=4), INTENT(OUT) :: sbuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN) :: nmin[reference]
INTEGER(KIND=4),INTENT(IN) :: nmax[reference]
INTEGER(KIND=4),INTENT(IN) :: idx[reference]
```

Format of the callback function in C:

```
int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int* nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table scallback Callback Function Parameters](#) gives the description of the callback function parameters.

scallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>sbuf</i>
<i>sbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$.

Description

The `vslsNewAbstractStream` function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b) . The function associates the stream with a single precision array `sbuf` and your callback function `scallback` that is intended for updating of `sbuf` content.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_BADARGS</code>	Parameter <code>n</code> is not positive.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for <code>stream</code> .
<code>VSL_ERROR_NULL_PTR</code>	Either buffer or callback function parameter is a NULL pointer.

vslDeleteStream

Deletes a random stream.

Syntax

Fortran:

```
status = vsldeletestream( stream )
```

C:

```
status = vslDeleteStream( &stream );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input/Output Parameters

Name	Type	Description
<code>stream</code>	FORTRAN 77: <code>INTEGER*4</code> <code>stream(2)</code> Fortran 90: <code>TYPE(VSL_STREAM_STATE),</code> <code>INTENT(OUT)</code>	Fortran: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the descriptor becomes invalid.
	C: <code>VSLStreamStatePtr*</code>	C: Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to <code>NULL</code> .

Description

The function deletes the random stream created by one of the initialization functions.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> parameter is a <code>NULL</code> pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.

vslCopyStream

Creates a copy of a random stream.

Syntax

Fortran:

```
status = vslcopystream( newstream, srcstream )
```

C:

```
status = vslCopyStream( &newstream, srcstream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
srcstream	FORTRAN 77: INTEGER*4 srcstream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	Fortran: Descriptor of the stream to be copied C: Pointer to the stream state structure to be copied

Output Parameters

Name	Type	Description
newstream	FORTRAN 77: INTEGER*4 newstream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT)	Copied random stream descriptor C: VSLStreamStatePtr*

Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>newstream</i> .

vslCopyStreamState

Creates a copy of a random stream state.

Syntax

Fortran:

```
status = vslcopystreamstate( deststream, srcstream )
```

C:

```
status = vslCopyStreamState( deststream, srcstream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>srcstream</i>	FORTRAN 77: INTEGER*4 <i>srcstream</i> (2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	Fortran: Descriptor of the destination stream where the state of <i>srcstream</i> stream is copied C: Pointer to the stream state structure, from which the state structure is copied

C: const VSLStreamStatePtr

Output Parameters

Name	Type	Description
<i>deststream</i>	FORTRAN 77: INTEGER*4 <i>deststream</i> (2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT)	Fortran: Descriptor of the stream with the state to be copied C: Pointer to the stream state structure where the stream state is copied

C: VSLStreamStatePtr

Description

The `vslCopyStreamState` function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike `vslCopyStream` function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `vslCopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>srcstream</i> or <i>deststream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.

VSL_RNG_ERROR_BRNGS_INCOMPATIBLE

BRNG associated with *srcstream* is not compatible with BRNG associated with *deststream*.

vslSaveStreamF

Writes random stream descriptive data, including stream state, to binary file.

Syntax

Fortran:

```
errstatus = vslsavestreamf( stream, fname )
```

C:

```
errstatus = vslSaveStreamF( stream, fname );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2)	Random stream to be written to the file
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	
	C: const VSLStreamStatePtr	
<i>fname</i>	FORTRAN 77: CHARACTER(*)	Fortran: File name specified as a C-style null-terminated string
	Fortran 90: CHARACTER(*), INTENT(IN)	C: File name specified as a Fortran-style character string
	C: const char*	

Output Parameters

Name	Type	Description
<i>errstatus</i>	Fortran: INTEGER C: int	Error status of the operation

Description

The `vslSaveStreamF` function writes the random stream descriptive data, including the stream state, to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. The random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. The random stream can be read from the binary file using the `vslLoadStreamF` function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>fname</i> or <i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.

vslLoadStreamF

Creates new stream and reads stream descriptive data, including stream state, from binary file.

Syntax

Fortran:

```
errstatus = vslloadstreamf( stream, fname )
```

C:

```
errstatus = vslLoadStreamF( &stream, fname );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>fname</i>	FORTRAN 77: CHARACTER(*) Fortran 90: CHARACTER(*), INTENT(IN) C: const char*	Fortran: File name specified as a C-style null-terminated string C: File name specified as a Fortran-style character string

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT) C: VSLStreamStatePtr*	Fortran: Descriptor of a new random stream C: Pointer to a new random stream
<i>errstatus</i>	Fortran: INTEGER C: int	Error status of the operation

Description

The `vslLoadStreamF` function creates a new stream and reads stream descriptive data, including the stream state, from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use `vslSaveStreamF` function.

CAUTION Calling `vslLoadStreamF` with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamF`, you should call the `vslDeleteStream` function first to deallocate the resources.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>fname</i> is a NULL pointer.
<code>VSL_RNG_ERROR_FILE_OPEN</code>	Indicates an error in opening the file.
<code>VSL_RNG_ERROR_FILE_WRITE</code>	Indicates an error in writing the file.
<code>VSL_RNG_ERROR_FILE_CLOSE</code>	Indicates an error in closing the file.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for internal needs.
<code>VSL_RNG_ERROR_BAD_FILE_FORMAT</code>	Unknown file format.
<code>VSL_RNG_ERROR_UNSUPPORTED_FILE_VER</code>	File format version is unsupported.
<code>VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPP</code>	Non-deterministic random number generator is not supported.

`vslSaveStreamM`

Writes random stream descriptive data, including stream state, to a memory buffer.

Syntax

Fortran:

```
errstatus = vslsavestreamm( stream, memptr )
```

C:

```
errstatus = vslSaveStreamM( stream, memptr );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2)	Random stream to be written to the memory

Name	Type	Description
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	
	C: const VSLStreamStatePtr	
<i>memptr</i>	FORTRAN 77: INTEGER*1 Fortran 90: INTEGER(KIND=1), DIMENSION(*), INTENT(IN) C: char*	Fortran: Memory buffer to save random stream descriptive data to C: Memory buffer to save random stream descriptive data to

Output Parameters

Name	Type	Description
<i>errstatus</i>	Fortran: INTEGER C: int	Error status of the operation

Description

The `vslSaveStreamM` function writes the random stream descriptive data, including the stream state, to the memory at *memptr*. Random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. The *memptr* parameter must be a valid pointer to the memory of size sufficient to hold the random stream *stream*. Use the service routine `vslGetStreamSize` to determine this amount of memory.

If the stream cannot be saved to the memory, *errstatus* has a non-zero value. The random stream can be read from the memory pointed by *memptr* using the `vslLoadStreamM` function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>memptr</i> or <i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is a NULL pointer.
VSL_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

`vslLoadStreamM`

Creates a new stream and reads stream descriptive data, including stream state, from the memory buffer.

Syntax

Fortran:

```
errstatus = vslloadstreamm( stream, memptr )
```

C:

```
errstatus = vslLoadStreamM( &stream, memptr );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>memptr</i>	FORTRAN 77: INTEGER*1 Fortran 90: INTEGER(KIND=1), DIMENSION(*), INTENT(IN)	Fortran: Memory buffer to load random stream descriptive data from C: Memory buffer to load random stream descriptive data from
	C: const char*	

Output Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(OUT)	Fortran: Descriptor of a new random stream C: Pointer to a new random stream
<i>errstatus</i>	Fortran: INTEGER C: int	Error status of the operation

Description

The `vslLoadStreamM` function creates a new stream and reads stream descriptive data, including the stream state, from the memory buffer. A new random stream is created using the stream descriptive data from the memory pointer by *memptr*. If the stream cannot be read (for example, *memptr* is invalid), *errstatus* has a non-zero value. To save random stream to the memory, use `vslSaveStreamM` function. Use the service routine `vslGetStreamSize` to determine the amount of memory sufficient to hold the random stream.

CAUTION Calling `LoadStreamM` with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamM`, you should call the `vslDeleteStream` function first to deallocate the resources.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>memptr</i> is a NULL pointer.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for internal needs.
<code>VSL_RNG_ERROR_BAD_MEM_FORMAT</code>	Descriptive random stream format is unknown.
<code>VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPP</code>	Non-deterministic random number generator is not supported.

`vslGetStreamSize`

Computes size of memory necessary to hold the random stream.

Syntax

Fortran:

```
memsize = vslgetstreamsize( stream )
```

C:

```
memsize = vslGetStreamSize( stream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN) C: const VSLStreamStatePtr	Random stream

Output Parameters

Name	Type	Description
<i>memsize</i>	Fortran: INTEGER C: int	Amount of memory in bytes necessary to hold descriptive data of random stream <i>stream</i>

Description

The `vslGetStreamSize` function returns the size of memory in bytes which is necessary to hold the given random stream. Use the output of the function to allocate the buffer to which you will save the random stream by means of the `vslSaveStreamM` function.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is a NULL pointer.
<code>VSL_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.

`vslLeapfrogStream`

Initializes a stream using the leapfrog method.

Syntax

Fortran:

```
status = vslleapfrogstream( stream, k, nstreams )
```

C:

```
status = vslLeapfrogStream( stream, k, nstreams );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90

- C: mkl.h

Input Parameters

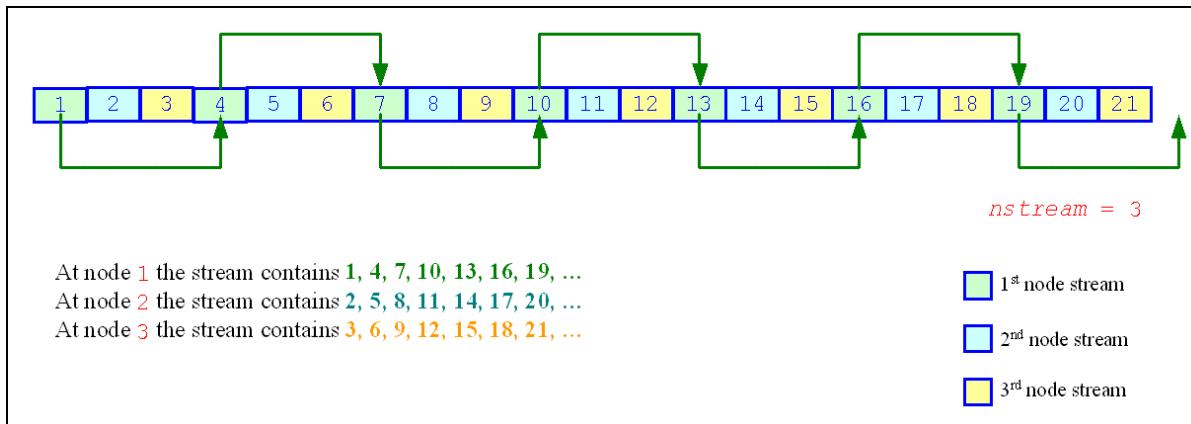

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream to which leapfrog method is applied C: Pointer to the stream state structure to which leapfrog method is applied
<i>k</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Index of the computational node, or stream number
<i>nstreams</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Largest number of computational nodes, or stride

Description

The `vslLeapfrogStream` function generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the *nstreams* buffers without generating the original random sequence with subsequent manual distribution.

One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes. The function initializes the original random stream (see [Figure "Leapfrog Method"](#)) to generate random numbers for the computational node *k*, $0 \leq k < nstreams$, where *nstreams* is the largest number of computational nodes used.

Leapfrog Method

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VSL Notes](#) for details.

For quasi-random basic generators, the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case *nstreams* parameter should be equal to the dimension of the quasi-random vector while *k* parameter should be the index of a component to be generated ($0 \leq k < nstreams$). Other parameters values are not allowed.

The following code examples illustrate the initialization of three independent streams using the leapfrog method:

Fortran 90 Code for Leapfrog Method

```
...
TYPE(VSL_STREAM_STATE) ::stream1
TYPE(VSL_STREAM_STATE) ::stream2
TYPE(VSL_STREAM_STATE) ::stream3

! Creating 3 identical streams
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
status = vslcopystream(stream2, stream1)
status = vslcopystream(stream3, stream1)

! Leapfrogging the streams
status = vslleapfrogstream(stream1, 0, 3)
status = vslleapfrogstream(stream2, 1, 3)
status = vslleapfrogstream(stream3, 2, 3)

! Generating random numbers
...
! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

C Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);

/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

vslSkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

Fortran:

```
status = vslskipaheadstream( stream, nskip )
```

C:

```
status = vslSkipAheadStream( stream, nskip );
```

Include Files

- Fortran: mkl.fi

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

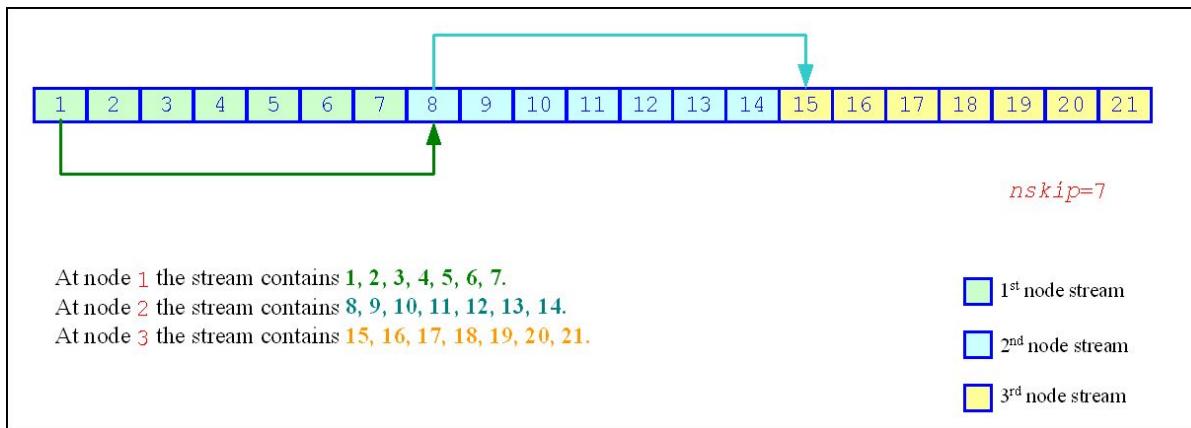

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2)	Fortran: Descriptor of the stream to which block-splitting method is applied
	Fortran 90: TYPE(VSL_STREAM_STATE), INTENT(IN)	C: Pointer to the stream state structure to which block-splitting method is applied
	C: VSLStreamStatePtr	
<i>nskip</i>	FORTRAN 77: INTEGER*4 <i>nskip</i> (2)	Number of skipped elements
	Fortran 90: INTEGER(KIND=8), INTENT(IN)	
	C: const long long int	

Description

The `vslSkipAheadStream` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by `vslSkipAheadStream` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see [Figure "Block-Splitting Method"](#)).

Block-Splitting Method

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VSL Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip NS quasi-random vectors, set the $nskip$ parameter equal to the $NS \times \text{DIMEN}$, where DIMEN is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is $2^{32}-1$, the library returns the `VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED` error code.

The following code examples illustrate how to initialize three independent streams using the `vslSkipAheadStream` function:

Fortran 90 Code for Block-Splitting Method

```
...
type(VSL_STREAM_STATE) ::stream1
type(VSL_STREAM_STATE) ::stream2
type(VSL_STREAM_STATE) ::stream3

! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)

! Skipping ahead by 7 elements the 2nd stream
status = vslcopystream(stream2, stream1);
status = vslskipaheadstream(stream2, 7);

! Skipping ahead by 7 elements the 3rd stream
status = vslcopystream(stream3, stream2);
status = vslskipaheadstream(stream3, 7);

! Generating random numbers
...
! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

C Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);

/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);

/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support the Skip-Ahead method.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the quasi-random number generator is exceeded.

vslGetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

Fortran:

```
brng = vslgetstreamstatebrng( stream )
```

C:

```
brng = vslGetStreamStateBrng( stream );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2)	Fortran: Descriptor of the stream state C: Pointer to the stream state structure
	Fortran 90: TYPE(VSL_STREAM_STATE), TINTENT(IN)	
	C: const VSLStreamStatePtr	

Output Parameters

Name	Type	Description
<i>brng</i>	Fortran: INTEGER C: int	Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error

Description

The `vslGetStreamStateBrng` function retrieves the index of a basic generator used for generation of a given random stream.

Return Values

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

vslGetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

Fortran:

```
nregbrngs = vslgetnumregbrngs( )
```

C:

```
nregbrngs = vslGetNumRegBrngs( void );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Output Parameters

Name	Type	Description
<i>nregbrngs</i>	Fortran: INTEGER C: int	Number of basic generators registered at the moment of the function call

Description

The `vslGetNumRegBrngs` function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by the `VSL_MAX_REG_BRNGS` parameter.

Distribution Generators

Intel MKL VSL routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence for both Fortran and C-interface and the explanation of input and output parameters. [Table "Continuous Distribution Generators"](#) and [Table "Discrete Distribution Generators"](#) list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	s, d	s, d	Uniform continuous distribution on the interval $[a, b]$
<code>vRngGaussian</code>	s, d	s, d	Normal (Gaussian) distribution
<code>vRngGaussianMV</code>	s, d	s, d	Multivariate normal (Gaussian) distribution
<code>vRngExponential</code>	s, d	s, d	Exponential distribution
<code>vRngLaplace</code>	s, d	s, d	Laplace distribution (double exponential distribution)
<code>vRngWeibull</code>	s, d	s, d	Weibull distribution
<code>vRngCauchy</code>	s, d	s, d	Cauchy distribution
<code>vRngRayleigh</code>	s, d	s, d	Rayleigh distribution
<code>vRngLognormal</code>	s, d	s, d	Lognormal distribution
<code>vRngGumbel</code>	s, d	s, d	Gumbel (extreme value) distribution
<code>vRngGamma</code>	s, d	s, d	Gamma distribution
<code>vRngBeta</code>	s, d	s, d	Beta distribution

Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	i	d	Uniform discrete distribution on the interval $[a, b]$

Type of Distribution	Data Types	BRNG Data Type	Description
vRngUniformBits	i	i	Underlying BRNG integer recurrence
vRngUniformBits 32	i	i	Uniformly distributed bits in 32-bit chunks
vRngUniformBits 64	i	i	Uniformly distributed bits in 64-bit chunks
vRngBernoulli	i	s	Bernoulli distribution
vRngGeometric	i	s	Geometric distribution
vRngBinomial	i	d	Binomial distribution
vRngHypergeometric	i	d	Hypergeometric distribution
vRngPoisson	i	s (for VSL_RNG_METHOD_POISSON_POISNORM) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for VSL_RNG_METHOD_POISSON_PTPE)	Poisson distribution
vRngPoissonV	i	s	Poisson distribution with varying mean
vRngNegBinomial	i	d	Negative binomial distribution, or Pascal distribution

Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval $[a,b]$ belong to this interval irrespective of what a and b values may be. Fast mode provides high performance of generation and also guarantees that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
vRngUniform	s, d
vRngExponential	s, d
vRngWeibull	s, d
vRngRayleigh	s, d
vRngLognormal	s, d
vRngGamma	s, d

Type of Distribution	Data Types
vRngBeta	s, d

See additional details about accurate and fast mode of random number generation in [VSL Notes](#).

New method names

The current version of Intel MKL has a modified structure of VSL RNG method names. (See [RNG Naming Conventions](#) for details.) The old names are kept for backward compatibility. The set correspondence between the new and legacy method names for VSL random number generators.

Method Names for Continuous Distribution Generators

RNG	Legacy Method Name	New Method Name
vRngUniform	VSL_METHOD_SUNIFORM_STD, VSL_METHOD_DUNIFORM_STD, VSL_METHOD_SUNIFORM_STD_ACCURATE, VSL_METHOD_DUNIFORM_STD_ACCURATE	VSL_RNG_METHOD_UNIFORM_STD, VSL_RNG_METHOD_UNIFORM_STD_ACCURATE
vRngGaussian	VSL_METHOD_SGAUSSIAN_BOXMULLER, VSL_METHOD_SGAUSSIAN_BOXMULLER2, VSL_METHOD_SGAUSSIAN_ICDF, VSL_METHOD_DGAUSSIAN_BOXMULLER, VSL_METHOD_DGAUSSIAN_BOXMULLER2, VSL_METHOD_DGAUSSIAN_ICDF	VSL_RNG_METHOD_GAUSSIAN_BOXMULLER, VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2, VSL_RNG_METHOD_GAUSSIAN_ICDF
vRngGaussianMV	VSL_METHOD_SGAUSSIANMV_BOXMULLER, VSL_METHOD_SGAUSSIANMV_BOXMULLER2, VSL_METHOD_SGAUSSIANMV_ICDF, VSL_METHOD_DGAUSSIANMV_BOXMULLER, VSL_METHOD_DGAUSSIANMV_BOXMULLER2, VSL_METHOD_DGAUSSIANMV_ICDF	VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER , VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER2, VSL_RNG_METHOD_GAUSSIANMV_ICDF
vRngExponential	VSL_METHOD_SEXPONENTIAL_ICDF, VSL_METHOD_DEXPOENTIAL_ICDF, VSL_METHOD_SEXPONENTIAL_ICDF_ACCURATE, VSL_METHOD_DEXPOENTIAL_ICDF_ACCURATE	VSL_RNG_METHOD_EXPONENTIAL_ICDF, VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACCURATE
vRngLaplace	VSL_METHOD_SLAPLACE_ICDF, VSL_METHOD_DLAPLACEL_ICDF	VSL_RNG_METHOD_LAPLACE_ICDF
vRngWeibull	VSL_METHOD_SWEBULL_ICDF, VSL_METHOD_DWEBULL_ICDF, VSL_METHOD_SWEBULL_ICDF_ACCURATE, VSL_METHOD_DWEBULL_ICDF_ACCURATE	VSL_RNG_METHOD_WEIBULL_ICDF, VSL_RNG_METHOD_WEIBULL_ICDF_ACCURATE
vRngCauchy	VSL_METHOD_SCAUCHY_ICDF, VSL_METHOD_DCAUCHY_ICDF	VSL_RNG_METHOD_CAUCHY_ICDF
vRngRayleigh	VSL_METHOD_SRAYLEIGH_ICDF, VSL_METHOD_DRAYLEIGH_ICDF, VSL_METHOD_SRAYLEIGH_ICDF_ACCURATE, VSL_METHOD_DRAYLEIGH_ICDF_ACCURATE	VSL_RNG_METHOD_RAYLEIGH_ICDF, VSL_RNG_METHOD_RAYLEIGH_ICDF_ACCURATE

RNG	Legacy Method Name	New Method Name
vRngLognorm al	VSL_METHOD_SLOGNORMAL_BOXMULLER2, VSL_METHOD_DLOGNORMAL_BOXMULLER2, VSL_METHOD_SLOGNORMAL_BOXMULLER2_A CCURATE, VSL_METHOD_DLOGNORMAL_BOXMULLER2_A CCURATE	VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2 , VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2 _ACCURATE
vRngGumbel	VSL_METHOD_SGUMBEL_ICDF, VSL_METHOD_DGUMBEL_ICDF	VSL_RNG_METHOD_GUMBEL_ICDF

vRngNegBinom ial	VSL_METHOD_INEGBINOMIAL_NBAR	VSL_RNG_METHOD_NEGBINOMIAL_NBAR

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

vRngUniform

Generates random numbers with uniform distribution.

Syntax

Fortran:

```
status = vsrnguniform( method, stream, n, r, a, b )
status = vdrnguniform( method, stream, n, r, a, b )
```

C:

```
status = vsRngUniform( method, stream, n, r, a, b );
status = vdRngUniform( method, stream, n, r, a, b );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Generation method; the specific values are as follows: VSL_RNG_METHOD_UNIFORM_STD VSL_RNG_METHOD_UNIFORM_STD_ACCURATE
	C: const int	Standard method.
<i>stream</i>	FORTRAN 77: INTEGER*4 Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN)	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Number of random values to be generated
<i>a</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL(KIND=4), INTENT(IN) for vsrnguniform REAL(KIND=8), INTENT(IN) for vdrnguniform C: const float for vsRngUniform const double for vdRngUniform	Left bound a

Name	Type	Description
<i>b</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL (KIND=4), INTENT (IN) for vsrnguniform REAL (KIND=8), INTENT (IN) for vdrnguniform C: const float for vsRngUniform const double for vdRngUniform	Right bound <i>b</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnguniform DOUBLE PRECISION for vdrnguniform Fortran 90: REAL (KIND=4), INTENT (OUT) for vsrnguniform REAL (KIND=8), INTENT (OUT) for vdrnguniform C: float* for vsRngUniform double* for vdRngUniform	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b]$

Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval $[a, b]$, where *a*, *b* are the left and right bounds of the interval, respectively, and $a, b \in \mathbb{R}$; $a < b$.

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \frac{1}{b-a}, & x \in [a, b] \\ 0, & x \notin [a, b] \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$f_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{x-a}{b-a}, & a \leq x \leq b, -\infty < x < +\infty \\ 1, & x \geq b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngGaussian

Generates normally distributed random numbers.

Syntax

Fortran:

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
status = vdrnggaussian( method, stream, n, r, a, sigma )
```

C:

```
status = vsRngGaussian( method, stream, n, r, a, sigma );
status = vdRngGaussian( method, stream, n, r, a, sigma );
```

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAUSSIAN_BOXMULLER VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2 VSL_RNG_METHOD_GAUSSIAN_ICDF
	C: const int	

Name	Type	Description
		See brief description of the methods <code>BOXMULLER</code> , <code>BOXMULLER2</code> , and <code>ICDF</code> in Table "Values of <method> in method parameter"
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL(KIND=4), INTENT(IN) for vsrnggaussian REAL(KIND=8), INTENT(IN) for vdrnggaussian C: const float for vsRngGaussian const double for vdRngGaussian	Mean value <i>a</i> .
<i>sigma</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL(KIND=4), INTENT(IN) for vsrnggaussian REAL(KIND=8), INTENT(IN) for vdrnggaussian C: const float for vsRngGaussian const double for vdRngGaussian	Standard deviation σ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrnggaussian REAL(KIND=8), INTENT(OUT) for vdrnggaussian C: float* for vsRngGaussian double* for vdRngGaussian	Vector of <i>n</i> normally distributed random numbers

Description

The `vRngGaussian` function generates random numbers with normal (Gaussian) distribution with mean value *a* and standard deviation σ , where

$$a, \sigma \in \mathbb{R} ; \sigma > 0.$$

The probability density function is given by:

$$f_{a, \sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x - a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a, \sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y - a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function $F_{a, \sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$$F_{a, \sigma}(x) = \Phi((x - a)/\sigma)$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.

VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngGaussianMV

Generates random numbers from multivariate normal distribution.

Syntax

Fortran:

```
status = vsrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
status = vdrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

C:

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

Description

The `vRngGaussianMV` function generates random numbers with *d*-variate normal (Gaussian) distribution with mean value *a* and variance-covariance matrix *c*, where $a \in \mathbb{R}^d$; *c* is a $d \times d$ symmetric positive-definite matrix. The probability density function is given by:

$$f_{a, c}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x - a)^T C^{-1}(x - a)),$$

where $x \in \mathbb{R}^d$.

Matrix *c* can be represented as $c = TT^T$, where *T* is a lower triangular matrix - Cholesky factor of *c*.

Instead of variance-covariance matrix *c* the generation routines require Cholesky factor of *c* in input. To compute Cholesky factor of matrix *c*, the user may call MKL LAPACK routines for matrix factorization: [?potrf](#) or [?pptrf](#) for `v?RngGaussianMV/v?rnggaussianmv` routines (? means either s or d for single and double precision respectively). See [Application Notes](#) for more details.

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VSL example file.

Using Cholesky Factorization Routines in Fortran

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in Fortran two-dimensional array	spotrf for vsrnggaussianmv	'U'	Upper triangle of T^T .
		dpotrf for vdrnggaussianmv		Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsrnggaussianmv	'L'	Upper triangle of T^T packed by rows into one-dimensional array.
		dpptrf for vdrnggaussianmv		

Using Cholesky Factorization Routines in C

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in C two-dimensional array	spotrf for vsRngGaussianMV	'U'	Upper triangle of T^T .
		dpotrf for vdRngGaussianMV		Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsRngGaussianMV	'L'	Upper triangle of T^T packed by rows into one-dimensional array.
		dpptrf for vdRngGaussianMV		

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngExponential

Generates exponentially distributed random numbers.

Syntax

Fortran:

```
status = vsrngexponential( method, stream, n, r, a, beta )
status = vdrngexponential( method, stream, n, r, a, beta )
```

C:

```
status = vsRngExponential( method, stream, n, r, a, beta );
status = vdRngExponential( method, stream, n, r, a, beta );
```

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrngexponential DOUBLE PRECISION for vdrngexponential Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrngexponential REAL(KIND=8), INTENT(OUT) for vdrngexponential C: float* for vsRngExponential double* for vdRngExponential	Vector of n exponentially distributed random numbers

Description

The `vRngExponential` function generates random numbers with exponential distribution that has displacement a and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp(-(x-a)/\beta), & x \geq a, -\infty < x < +\infty. \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngLaplace

Generates random numbers with Laplace distribution.

Syntax

Fortran:

```
status = vsrnglaplace( method, stream, n, r, a, beta )
status = vdrglaplace( method, stream, n, r, a, beta )
```

C:

```
status = vsRngLaplace( method, stream, n, r, a, beta );
status = vdRngLaplace( method, stream, n, r, a, beta );
```

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrnglaplace DOUBLE PRECISION for vdrnglaplace Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrnglaplace REAL(KIND=8), INTENT(OUT) for vdrnglaplace C: float* for vsRngLaplace double* for vdRngLaplace	Vector of <i>n</i> Laplace distributed random numbers

Description

The `vRngLaplace` function generates random numbers with Laplace distribution with mean value (or average) α and scalefactor β , where $\alpha, \beta \in \mathbb{R}$; $\beta > 0$. The scalefactor value determines the standard deviation as

.....

The probability density function is given by:

$$f_{\alpha, \beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x - \alpha|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{\alpha, \beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x - \alpha|}{\beta}\right), & x \geq \alpha \\ 1 - \frac{1}{2} \exp\left(-\frac{|x - \alpha|}{\beta}\right), & x < \alpha \end{cases}, -\infty < x < +\infty.$$

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`
`VSL_ERROR_NULL_PTR`

Indicates no error, execution is successful.
stream is a NULL pointer.

VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngWeibull

Generates Weibull distributed random numbers.

Syntax

Fortran:

```
status = vsrngweibull( method, stream, n, r, alpha, a, beta )
status = vdrngweibull( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngWeibull( method, stream, n, r, alpha, a, beta );
status = vdRngWeibull( method, stream, n, r, alpha, a, beta );
```

Description

The `vRngWeibull` function generates Weibull distributed random numbers with displacement a , scalefactor β , and shape α , where $\alpha, \beta, a \in R ; \alpha > 0, \beta > 0$.

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x-a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x-a}{\beta}\right)^\alpha\right), & x \geq a, -\infty < x < +\infty. \\ 0, & x < a \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngCauchy

Generates Cauchy distributed random values.

Syntax

Fortran:

```
status = vsrngcauchy( method, stream, n, r, a, beta )
```

```
status = vdrngcauchy( method, stream, n, r, a, beta )
```

C:

```
status = vsRngCauchy( method, stream, n, r, a, beta );
```

```
status = vdRngCauchy( method, stream, n, r, a, beta );
```

Description

The function generates Cauchy distributed random numbers with displacement a and scalefactor β , where a , $\beta \in \mathbb{R}$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta \left(1 + \left(\frac{x-a}{\beta}\right)^2\right)}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{\alpha,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan\left(\frac{x - \alpha}{\beta}\right), \quad -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

Description

The `vRngRayleigh` function generates Rayleigh distributed random numbers with displacement α and scalefactor β , where $\alpha, \beta \in \mathbb{R} ; \beta > 0$.

The Rayleigh distribution is a special case of the [Weibull](#) distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{\alpha, \beta}(x) = \begin{cases} \frac{2(x - \alpha)}{\beta^2} \exp\left(-\frac{(x - \alpha)^2}{\beta^2}\right), & x \geq \alpha, -\infty < x < +\infty. \\ 0, & x < \alpha \end{cases}$$

The cumulative distribution function is as follows:

$$F_{\alpha, \beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x - \alpha)^2}{\beta^2}\right), & x \geq \alpha, -\infty < x < +\infty. \\ 0, & x < \alpha \end{cases}$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngLognormal

Generates lognormally distributed random numbers.

Syntax

Fortran:

```
status = vsrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

```
status = vdrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

C:

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

```
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

Description

The `vRngLognormal` function generates lognormally distributed random numbers with average of distribution a and standard deviation σ of subject normal distribution, displacement b , and scalefactor β , where $a, \sigma, b, \beta \in \mathbb{R}$; $\sigma > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x - b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x - b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi((\ln((x - b)/\beta) - a)/\sigma), & x > b \\ 0, & x \leq b \end{cases}$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.

VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngGumbel

Generates Gumbel distributed random values.

Syntax

Fortran:

```
status = vsrnggumbel( method, stream, n, r, a, beta )
status = vdrgngumbel( method, stream, n, r, a, beta )
```

C:

```
status = vsRngGumbel( method, stream, n, r, a, beta );

Description

The `vRngGamma` function generates random numbers with gamma distribution that has shape parameter α , displacement a , and scale parameter β , where α, β , and $a \in R$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha, a, \beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, \quad -\infty < x < +\infty$$

where $\Gamma(\alpha)$ is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha, a, \beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y - a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, \quad -\infty < x < +\infty$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngBeta

Generates beta distributed random values.

Syntax

Fortran:

```
status = vsrngbeta( method, stream, n, r, p, q, a, beta )
status = vdrngbeta( method, stream, n, r, p, q, a, beta )
```

C:

```
status = vsRngBeta( method, stream, n, r, p, q, a, beta );
status = vdRngBeta( method, stream, n, r, p, q, a, beta );
```

	REAL(KIND=8), INTENT(IN) for vdrngbeta	
	C: const float for vsRngBeta const double for vdRngBeta	

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: REAL for vsrngbeta	Vector of <i>n</i> random numbers with beta distribution
	DOUBLE PRECISION for vdrngbeta	
	Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrngbeta	
	REAL(KIND=8), INTENT(OUT) for vdrngbeta	
	C: float* for vsRngBeta double* for vdRngBeta	

Description

The `vRngBeta` function generates random numbers with beta distribution that has shape parameters p and q , displacement a , and scale parameter β , where p, q, a , and $\beta \in \mathbb{R}$; $p > 0, q > 0, \beta > 0$.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p, q)\beta^{p+q-1}} (x - a)^{p-1}(\beta + a - x)^{q-1}, & a \leq x < a + \beta \\ 0, & x < a, x \geq a + \beta \end{cases}, \quad -\infty < x < \infty,$$

where $B(p, q)$ is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p, q)\beta^{p+q-1}} (y - a)^{p-1}(\beta + a - y)^{q-1} dy, & a \leq x < a + \beta, -\infty < x < \infty. \\ 1, & x \geq a + \beta \end{cases}$$

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

vRngUniform

Generates random numbers uniformly distributed over the interval $[a, b]$.

Syntax

Fortran:

```
status = virnguniform( method, stream, n, r, a, b )
```

C:

```
status = viRngUniform( method, stream, n, r, a, b );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Generation method; the specific value is as follows: VSL_RNG_METHOD_UNIFORM_STD Standard method. Currently there is only one method for this distribution generator.
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER	Number of random values to be generated

Name	Type	Description
	Fortran 90: INTEGER, INTENT (IN)	
	C: const int	
a	FORTRAN 77: INTEGER*4	Left interval bound a
	Fortran 90: INTEGER (KIND=4), INTENT (IN)	
	C: const int	
b	FORTRAN 77: INTEGER*4	Right interval bound b
	Fortran 90: INTEGER (KIND=4), INTENT (IN)	
	C: const int	

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER*4	Vector of n random numbers uniformly distributed over the
	Fortran 90: INTEGER (KIND=4), INTENT (OUT)	interval $[a, b]$
	C: int*	

Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval $[a, b]$, where a, b are the left and right bounds of the interval respectively, and $a, b \in \mathbb{Z}; a < b$.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in \mathbb{R} \\ 1, & x \geq b \end{cases}$$

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngUniformBits

Generates bits of underlying BRNG integer recurrence.

Syntax

Fortran:

```
status = virnguniformbits( method, stream, n, r )
```

C:

```
status = viRngUniformBits( method, stream, n, r );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS_STD
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: unsigned int*	<p>Fortran: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>wordsize</i> of the structure <code>VSL_BRNG_PROPERTIES</code>. The total number of bits that are actually used to store the value are contained in the field <i>nbits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of <code>VSLBRngProperties</code>.</p> <p>C: Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure <code>VSLRngProperties</code>. The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of <code>VSLRngProperties</code>.</p>

Description

The `vRngUniformBits` function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit *LCG* only 24 higher bits of an integer value can be considered random. See [VSL Notes](#) for details.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

`vRngUniformBits32`

Generates uniformly distributed bits in 32-bit chunks.

Syntax

Fortran:

```
status = virnguniformbits32( method, stream, n, r )
```

C:

```
status = viRngUniformBits32( method, stream, n, r );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS32_STD
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER (KIND=4), INTENT (OUT) C: unsigned int*	Fortran: Vector of <i>n</i> 32-bit random integer numbers with uniform bit distribution. C: Vector of <i>n</i> 32-bit random integer numbers with uniform bit distribution.

Description

The vRngUniformBits32 function generates uniformly distributed bits in 32-bit chunks. Unlike vRngUniformBits, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, vRngUniformBits32 is designed to ensure each bit in the 32-bit chunk is uniformly distributed. See [VSL Notes](#) for details.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngUniformBits64

Generates uniformly distributed bits in 64-bit chunks.

Syntax

Fortran:

```
status = virnguniformbits64( method, stream, n, r )
```

C:

```
status = viRngUniformBits64( method, stream, n, r );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS64_STD
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*8 Fortran 90: INTEGER (KIND=8), INTENT(OUT)	Fortran: Vector of <i>n</i> 64-bit random integer numbers with uniform bit distribution.
	C: unsigned long long*	C: Vector of <i>n</i> 64-bit random integer numbers with uniform bit distribution.

Description

The `vRngUniformBits64` function generates uniformly distributed bits in 64-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits64` is designed to ensure each bit in the 64-bit chunk is uniformly distributed. See [VSL Notes](#) for details.

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BRNG_NOT_SUPPORTED</code>	BRNG is not supported by the function.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED_ED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

`vRngBernoulli`

Generates Bernoulli distributed random values.

Syntax

Fortran:

```
status = virngbernoulli( method, stream, n, r, p )
```

C:

```
status = viRngBernoulli( method, stream, n, r, p );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN)	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_BERNOULLI_ICDF</code>
	C: const int	Inverse cumulative distribution function method.

Name	Type	Description
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2)	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
	Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN)	
	C: VSLStreamStatePtr	
<i>n</i>	FORTRAN 77: INTEGER	Number of random values to be generated
	Fortran 90: INTEGER, INTENT(IN)	
	C: const int	
<i>p</i>	FORTRAN 77: DOUBLE PRECISION	Success probability <i>p</i> of a trial
	Fortran 90: REAL(KIND=8), INTENT(IN)	
	C: const double	

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4	Vector of <i>n</i> Bernoulli distributed random values
	Fortran 90: INTEGER(KIND=4), INTENT(OUT)	
	C: int*	

Description

The vRngBernoulli function generates Bernoulli distributed random numbers with probability *p* of a single trial success, where

$$p \in R; 0 \leq p \leq 1.$$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success *p*, and to 0 with probability $1 - p$.

The probability distribution is given by:

$$P(X = 1) = p$$

$$P(X = 0) = 1 - p$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in R. \\ 1, & x \geq 1 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngGeometric

Generates geometrically distributed random values.

Syntax

Fortran:

```
status = virnggeometric( method, stream, n, r, p )
```

C:

```
status = viRngGeometric( method, stream, n, r, p );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Generation method. The specific value is as follows: VSL_RNG_METHOD_GEOMETRIC_ICDF Inverse cumulative distribution function method.
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of random values to be generated

Name	Type	Description
p	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double	Success probability p of a trial

Output Parameters

Name	Type	Description
r	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*	Vector of n geometrically distributed random values

Description

The `vRngGeometric` function generates geometrically distributed random numbers with probability p of a single trial success, where $p \in R$; $0 < p < 1$.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is p .

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \geq x \in R. \end{cases}$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngBinomial

Generates binomially distributed random numbers.

Syntax

Fortran:

```
status = virngbinomial( method, stream, n, r, ntrial, p )
```

C:

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Generation method. The specific value is as follows: VSL_RNG_METHOD_BINOMIAL_BTPE See brief description of the BTPE method in Table "Values of <method> in method parameter" .
<i>stream</i>	FORTRAN 77: INTEGER*4 <i>stream</i> (2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of random values to be generated
<i>ntrial</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Number of independent trials m
<i>p</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double	Success probability p of a single trial

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER (KIND=4), INTENT (OUT) C: int*	Vector of <i>n</i> binomially distributed random values

Description

The vRngBinomial function generates binomially distributed random numbers with number of independent Bernoulli trials *m*, and with probability *p* of a single trial success, where $p \in R$; $0 \leq p \leq 1$, $m \in N$.

A binomially distributed variate represents the number of successes in *m* independent Bernoulli trials with probability of a single trial success *p*.

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1 - p)^{m-k}, & 0 \leq x < m, x \in R \\ 1, & x \geq m \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngHypergeometric

Generates hypergeometrically distributed random values.

Syntax**Fortran:**

```
status = virnghypergeometric( method, stream, n, r, l, s, m )
```

C:

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Generation method. The specific value is as follows: VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE
<i>stream</i>	FORTRAN 77: INTEGER*4 stream(2) Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of random values to be generated
<i>l</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Lot size <i>l</i>
<i>s</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(IN) C: const int	Size of sampling without replacement <i>s</i>
<i>m</i>	FORTRAN 77: INTEGER*4	Number of marked elements <i>m</i>

Name	Type	Description
	Fortran 90: INTEGER(KIND=4), INTENT(IN)	
	C: const int	

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4	Vector of n hypergeometrically distributed random values
	Fortran 90: INTEGER(KIND=4), INTENT(OUT)	
	C: int*	

Description

The `vRngHypergeometric` function generates hypergeometrically distributed random values with lot size l , size of sampling s , and number of marked elements in the lot m , where $l, m, s \in \mathbb{N} \cup \{0\}$; $l \geq \max(s, m)$.

Consider a lot of l elements comprising m "marked" and $l-m$ "unmarked" elements. A trial sampling without replacement of exactly s elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of s elements contains exactly k marked elements.

The probability distribution is given by:

$$P(X = k) = \frac{\binom{m}{k} \binom{l-m}{s-k}}{\binom{l}{s}}$$

, $k \in \{\max(0, s + m - l), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0,s+m-l)}^{\lfloor x \rfloor} \frac{\binom{m}{k} \binom{l-m}{s-k}}{\binom{l}{s}}, & \max(0, s + m - l) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.

<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngPoisson

Generates Poisson distributed random values.

Syntax

Fortran:

```
status = virngpoisson( method, stream, n, r, lambda )
```

C:

```
status = viRngPoisson( method, stream, n, r, lambda );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific values are as follows: <code>VSL_RNG_METHOD_POISSON_PTPE</code> <code>VSL_RNG_METHOD_POISSON_POISNORM</code> See brief description of the PTPE and POISNORM methods in Table "Values of <method> in method parameter" .
<i>stream</i>	FORTRAN 77: INTEGER*4 <code>stream(2)</code> Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>lambda</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT (IN) C: const double	Distribution parameter λ .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER (KIND=4), INTENT (OUT)	Vector of n Poisson distributed random values
	C: int*	

Description

The `vRngPoisson` function generates Poisson distributed random numbers with distribution parameter λ , where $\lambda \in R$; $\lambda > 0$.

The probability distribution is given by:

$$\dots i ! \dots \lambda^k e^{-\lambda} / k! \dots$$

$k \in \{0, 1, 2, \dots\}$.

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0, x \in R \\ 0, & x < 0 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngPoissonV

Generates Poisson distributed random values with varying mean.

Syntax

Fortran:

```
status = virngpoissonv( method, stream, n, r, lambda )
```

C:

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_POISSONV_POISNORM</code> See brief description of the POISNORM method in Table "Values of <method> in <i>method</i> parameter"
<i>stream</i>	FORTRAN 77: INTEGER*4 <code>stream(2)</code> Fortran 90: TYPE (VSL_STREAM_STATE), INTENT(IN) C: VSLStreamStatePtr	Fortran: Descriptor of the stream state structure. C: Pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT(IN) C: const int	Number of random values to be generated
<i>lambda</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL(KIND=8), INTENT(IN) C: const double*	Array of <i>n</i> distribution parameters λ_i .

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER(KIND=4), INTENT(OUT) C: int*	Vector of <i>n</i> Poisson distributed random values

Description

The `vRngPoissonV` function generates n Poisson distributed random numbers $x_i (i = 1, \dots, n)$ with distribution parameter λ_i , where $\lambda_i \in R; \lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k e^{-\lambda_i}}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0, x \in R \\ 0, & x < 0 \end{cases}$$

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<code>stream</code> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<code>stream</code> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

vRngNegBinomial

Generates random numbers with negative binomial distribution.

Syntax

Fortran:

```
status = virngnegbinomial( method, stream, n, r, a, p )
```

C:

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

Include Files

- Fortran: `mkl.fi`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>method</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Generation method. The specific value is: <code>VSL_RNG_METHOD_NEGBINOMIAL_NBAR</code> See brief description of the NBAR method in Table "Values of <method> in method parameter"
<i>stream</i>	FORTRAN 77: INTEGER*4 <code>stream(2)</code> Fortran 90: TYPE (VSL_STREAM_STATE), INTENT (IN) C: VSLStreamStatePtr	Fortran: descriptor of the stream state structure. C: pointer to the stream state structure
<i>n</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, INTENT (IN) C: const int	Number of random values to be generated
<i>a</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL (KIND=8), INTENT (IN) C: const double	The first distribution parameter <i>a</i>
<i>p</i>	FORTRAN 77: DOUBLE PRECISION Fortran 90: REAL (KIND=8), INTENT (IN) C: const double	The second distribution parameter <i>p</i>

Output Parameters

Name	Type	Description
<i>r</i>	FORTRAN 77: INTEGER*4 Fortran 90: INTEGER (KIND=4), INTENT (OUT) C: int*	Vector of <i>n</i> random values with negative binomial distribution.

Description

The `vRngNegBinomial` function generates random numbers with negative binomial distribution and distribution parameters *a* and *p*, where *p*, *a* $\in \mathbb{R}$; $0 < p < 1$; $a > 0$.

If the first distribution parameter *a* $\in \mathbb{N}$, this distribution is the same as Pascal distribution. If *a* $\in \mathbb{N}$, the distribution can be interpreted as the expected time of *a*-th success in a sequence of Bernoulli trials, when the probability of success is *p*.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^k p^a (1 - p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

Advanced Service Routines

This section describes service routines for registering a user-designed basic generator ([vslRegisterBrng](#)) and for obtaining properties of the previously registered basic generators ([vslGetBrngProperties](#)). See [VSL Notes](#) ("Basic Generators" section of VSL Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

Data types

The Advanced Service routines refer to a structure defining the properties of the basic generator. This structure is described in Fortran 90 as follows:

```
TYPE VSL_BRNG_PROPERTIES
  INTEGER streamstate
  INTEGER nseeds
  INTEGER includeszero
  INTEGER wordsize
  INTEGER nbits
  INTEGER nitstream
  INTEGER sbrng
  INTEGER dbrng
  INTEGER ibrng
END TYPE VSL_BRNG_PROPERTIES
```

The C version is as follows:

```
typedef struct _VSLBRngProperties {
    int StreamStateSize;
    int NSeeds;
    int IncludesZero;
    int WordSize;
    int NBits;
    InitStreamPtr InitStream;
    sBRngPtr sBRng;
    dBRngPtr dBRng;
    iBRngPtr iBRng;
} VSLBRngProperties;
```

The following table provides brief descriptions of the fields engaged in the above structure:

Field Descriptions

Field	Short Description
Fortran: streamstatesize C: StreamStateSize	The size, in bytes, of the stream state structure for a given basic generator.
Fortran: nseeds C: NSeeds	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
Fortran: includeszero C: IncludesZero	Flag value indicating whether the generator can produce a random 0.
Fortran: wordsize C: WordSize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
Fortran: nbits C: NBits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, wordsize/WordSize is equal to 8 (number of bytes used to store the random value), while nbits/NBits contains the actual number of bits occupied by the value (in this example, 48).
Fortran: initstream C: InitStream	Contains the pointer to the initialization routine of a given basic generator.
Fortran: sbrng C: sBRng	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval (a, b) (<i>real</i> in Fortran and <i>float</i> in C).
Fortran: dbrng C: dBRng	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval (a, b) (<i>double PRECISION</i> in Fortran and <i>double</i> in C).
Fortran: ibrng C: iBRng	Contains the pointer to the basic generator of integer numbers with uniform bit distribution ¹ (<i>INTEGER</i> in Fortran and <i>unsigned int</i> in C).

¹A specific generator that permits operations over single bits and bit groups of random numbers.

vslRegisterBrng

Registers user-defined basic generator.

Syntax

C:

```
brng = vslRegisterBrng( &properties );
```

Include Files

- C: mkl.h

Input Parameters

Name	Type	Description
properties	C: const VSLBRngProperties*	Pointer to the structure containing properties of the basic generator to be registered

NOTE This function is not supported for Fortran. If you need to use a user-defined generator in Fortran, use an abstract basic random generator and abstract stream as described in the VSL Notes.

Output Parameters

Name	Type	Description
brng	C: int	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

Description

An example of a registration procedure can be found in the respective directory of the VSL examples.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	Bad value in StreamStateSize field.
VSL_RNG_ERROR_BAD_WORD_SIZE	Bad value in WordSize field.
VSL_RNG_ERROR_BAD_NSEEDS	Bad value in NSeeds field.
VSL_RNG_ERROR_BAD_NBITS	Bad value in NBits field.
VSL_ERROR_NULL_PTR	At least one of the fields iBrng, dBrng, sBrng or InitStream is a NULL pointer.

vslGetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

Fortran:

```
status = vslgetbrngproperties( brng, properties )
```

C:

```
status = vslGetBrngProperties( brng, &properties );
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>brng</i>	Fortran: INTEGER(KIND=4), INTENT(IN) C: const int	Number (index) of the registered basic generator; used for identification. See specific values in Table "Values of <i>brng</i> parameter" . Negative values indicate the registration error.

NOTE FORTRAN 77 support is unavailable for this function.

Output Parameters

Name	Type	Description
<i>properties</i>	Fortran: TYPE(VSL_BRNG_PROPERTIES), INTENT(OUT) C: VSLBRngProperties*	Pointer to the structure containing properties of the generator with number <i>brng</i>

Description

The `vslGetBrngProperties` function returns a structure with properties of a given basic generator.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.

Formats for User-Designed Generators

To register a user-designed basic generator using `vslRegisterBrng` function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See below recommendations on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VSL examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] );
typedef int(*sBrngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );
typedef int(*dBrngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );
typedef int(*iBrngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

InitStream

C:

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] )
{
    /* Initialize the stream */
    ...
} /* MyBrngInitStream */
```

Description

The initialization routine of a user-designed generator must initialize *stream* according to the specified initialization *method*, initial conditions *params* and the argument *n*. The value of *method* determines the initialization method to be used.

- If *method* is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.
- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_ERROR_SKIPAHEAD_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of `vslLeapfrogStream` and `vslSkipAheadStream`, respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

C:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;
- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in *LCG(a, c, m)*, apart from the initial conditions, two more fields should be specified: the value of the multiplier a^k and the value of the increment $(a^k - 1) c / (a - 1)$.

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VSL examples.

iBRng

C:

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
       store only random number */
    for( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* iMyBrng */
```

NOTE When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector *r* correctly. For example, storing one 64-bit value requires two elements of *r*, the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of *r* to store a 128-bit value.

sBRng

C:

```
int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int i; /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */
```

dBRng

C:

```
int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i; /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */
```

Convolution and Correlation

Intel MKL VSL provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see the [Mathematical Notation and Definitions](#) section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM® ESSL library:

```
SCONF, SCORF
SCOND, SCORD
SDCON, SDCOR
DDCON, DDCOR
SDDCON, SDDCOR.
```

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources for Fortran and C. To reuse them, use the following directories:

```
$(MKL)/examples/vslc/essl/vsl_wrappers
$(MKL)/examples/vslf/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers. You can find the examples in the following directories:

```
$(MKL)/examples/vslc/essl
$(MKL)/examples/vslf/essl
```

The convolution and correlation API provides interfaces for FORTRAN 77, Fortran 90 and C/89 languages. You may use the C/89 interface also with later versions of C or C++, or Fortran 90 interface with programs written in Fortran 95.

For users of the C/C++ and Fortran languages, the `mkl_vsl.h`, `mkl_vsl.f90`, and `mkl_vsl.f77` headers are provided. All header files are found under the directory:

```
 ${MKL}/include
```

See more details about the Fortran header in [Random Number Generators](#) section of this chapter.

The convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All the Intel MKL VSL convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Naming Conventions

The names of Fortran routines in the convolution and correlation API are written in lowercase (`vslsconvexec`), while the names of Fortran types and constants are written in uppercase. The names are not case-sensitive.

In C, the names of routines, types, and constants are case-sensitive and can be lowercase and uppercase (`vslsConvExec`).

The names of routines have the following structure:

`vsl[datatype] {Conv|Corr}<base name>` for the C interface

`vsl[datatype] {conv|corr}<base name>` for the Fortran interface

where

- `vsl` is a prefix indicating that the routine belongs to Vector Statistical Library of Intel® MKL.
- `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).
- `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.
- `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
FORTRAN 77: INTEGER*4 task (2)	Pointer to a task descriptor for convolution
Fortran 90: TYPE(VSL_CONV_TASK)	
C: VSLConvTaskPtr	
FORTRAN 77: INTEGER*4 task (2)	Pointer to a task descriptor for correlation
Fortran 90: TYPE(VSL_CORR_TASK)	
C: VSLCorrTaskPtr	
FORTRAN 77: REAL*4	Input/output user real data in single precision
Fortran 90: REAL (KIND=4)	
C: float	
FORTRAN 77: REAL*8	Input/output user real data in double precision
Fortran 90: REAL (KIND=8)	
C: double	
FORTRAN 77: COMPLEX*8	Input/output user complex data in single precision
Fortran 90: COMPLEX (KIND=4)	
C: MKL_Complex8	
FORTRAN 77: COMPLEX*16	Input/output user complex data in double precision
Fortran 90: COMPLEX (KIND=8)	
C: MKL_Complex16	
FORTRAN 77: INTEGER	All other data
Fortran 90: INTEGER	
C: int	

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE The actual size of the generic integer type is platform-dependent. Before you compile your application, set an appropriate byte size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL User's Guide*.

Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
<i>job</i>	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
<i>type</i>	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
<i>precision</i>	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays <i>x,y,z</i> .
<i>mode</i>	explicit	integer	None	Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See SetMode for the list of named constants for this parameter.
<i>method</i>	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.
<i>internal_precision</i>	optional	integer	Set equal to the value of <i>precision</i>	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See SetInternalPrecision for the list of named constants for this parameter.
<i>dims</i>	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays <i>x,y,z</i> . Can be in the range from 1 to 7.
<i>x,y</i>	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.
<i>z</i>	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
<i>xshape,</i> <i>yshape,</i> <i>zshape</i>	explicit	integer arrays	None	Define shapes of the arrays <i>x, y, z</i> . See Data Allocation for more information.
<i>xstride,</i> <i>ystride,</i> <i>zstride</i>	explicit	integer arrays	None	Define strides within arrays <i>x, y, z</i> , that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.
<i>start</i>	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See SetStart and Data Allocation for more information.

Name	Category	Type	Default Value Label	Description
<i>decimation</i>	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See SetDecimation and Data Allocation for more information.

Users of the C or C++ language may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the Fortran-style "by columns" representation of multi-dimensional arrays.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings.

An error can be caused by invalid parameter values, a system fault like a memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, the constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation, which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor is terminated and the task keeps the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The status codes are given symbolic names defined in the respective header files. For the C/C++ interface, these names are defined as macros via the `#define` statements, and for the Fortran interface as integer constants via the `PARAMETER` operators.

If there is no error, the `VSL_STATUS_OK` status is returned, which is defined as zero:

```
C/C++:           #define VSL_STATUS_OK 0
F90/F95:         INTEGER(KIND=4) VSL_STATUS_OK
                  PARAMETER(VSL_STATUS_OK = 0)
F77:             INTEGER*4 VSL_STATUS_OK
                  PARAMETER(VSL_STATUS_OK = 0)
```

In case of an error, a non-zero error code is returned, which indicates the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files for both C/C++ and Fortran languages.

Convolution/Correlation Status Codes

Status Code	Description
<code>VSL_CC_ERROR_NOT_IMPLEMENTED</code>	Requested functionality is not implemented.
<code>VSL_CC_ERROR_ALLOCATION_FAILURE</code>	Memory allocation failure.
<code>VSL_CC_ERROR_BAD_DESCRIPTOR</code>	Task descriptor is corrupted.

Status Code	Description
VSL_CC_ERROR_SERVICE_FAILURE	A service function has failed.
VSL_CC_ERROR_EDIT_FAILURE	Failure while editing the task.
VSL_CC_ERROR_EDIT_PROHIBITED	You cannot edit this parameter.
VSL_CC_ERROR_COMMIT_FAILURE	Task commitment has failed.
VSL_CC_ERROR_COPY_FAILURE	Failure while copying the task.
VSL_CC_ERROR_DELETE_FAILURE	Failure while deleting the task.
VSL_CC_ERROR_BAD_ARGUMENT	Bad argument or task parameter.
VSL_CC_ERROR_JOB	Bad parameter: <i>job</i> .
SL_CC_ERROR_KIND	Bad parameter: <i>kind</i> .
VSL_CC_ERROR_MODE	Bad parameter: <i>mode</i> .
VSL_CC_ERROR_METHOD	Bad parameter: <i>method</i> .
VSL_CC_ERROR_TYPE	Bad parameter: <i>type</i> .
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: <i>external_precision</i> .
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: <i>internal_precision</i> .
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: <i>dims</i> .
VSL_CC_ERROR_XSHAPE	Bad parameter: <i>xshape</i> .
VSL_CC_ERROR_YSHAPE	Bad parameter: <i>yshape</i> .
VSL_CC_ERROR_ZSHAPE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_CC_ERROR_ZSHAPE	Bad parameter: <i>zshape</i> .
VSL_CC_ERROR_XSTRIDE	Bad parameter: <i>xstride</i> .
VSL_CC_ERROR_YSTRIDE	Bad parameter: <i>ystride</i> .
VSL_CC_ERROR_ZSTRIDE	Bad parameter: <i>zstride</i> .
VSL_CC_ERROR_X	Bad parameter: <i>x</i> .
VSL_CC_ERROR_Y	Bad parameter: <i>y</i> .
VSL_CC_ERROR_Z	Bad parameter: <i>z</i> .
VSL_CC_ERROR_START	Bad parameter: <i>start</i> .
VSL_CC_ERROR_DECIMATION	Bad parameter: <i>decimation</i> .
VSL_CC_ERROR_OTHER	Another error.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. No additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form constructors but also assign particular data to the first operand vector used in the convolution or correlation operation (stored in array x).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array x against different vectors held in array y . This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Each constructor routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

The [Table "Task Constructors"](#) lists available task constructors:

Task Constructors

Routine	Description
<code>vslConvNewTask/vslCorrNewTask</code>	Creates a new convolution or correlation task descriptor for a multidimensional case.
<code>vslConvNewTask1D/vslCorrNewTask1D</code>	Creates a new convolution or correlation task descriptor for a one-dimensional case.
<code>vslConvNewTaskX/vslCorrNewTaskX</code>	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
<code>vslConvNewTaskX1D/vslCorrNewTaskX1D</code>	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

[vslConvNewTask/vslCorrNewTask](#)

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslcconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslscorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslcorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslccorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzcorrnewtask(task, mode, dims, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
```

```

status = vslDConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslCConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslDCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslCCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzCorrNewTask(task, mode, dims, xshape, yshape, zshape);

```

Input Parameters

Name	Type	Description
mode	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
dims	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
xshape	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the input data for the source array <i>x</i> . See Data Allocation for more information.
yshape	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the input data for the source array <i>y</i> . See Data Allocation for more information.
zshape	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION(*) C: const int[]	Defines the shape of the output data to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<code>task</code>	FORTRAN 77: INTEGER*4 Fortran 90: <code>TYPE(VSL_CONV_TASK) for</code> <code>vslsconvnewtask,</code> <code>vsldconvnewtask,</code> <code>vslccconvnewtask,</code> <code>vslzconvnewtask</code> C: VSLConvTaskPtr* for <code>vslsConvNewTask,</code> <code>vsldConvNewTask,</code> <code>vslcConvNewTask,</code> <code>vslzConvNewTask</code> C++: VSLConvTask* for <code>vslsConvNewTask,</code> <code>vsldConvNewTask,</code> <code>vslcConvNewTask,</code> <code>vslzConvNewTask</code>	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<code>status</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to <code>VSL_STATUS_OK</code> if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTask/vslCorrNewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

The parameters `xshape`, `yshape`, and `zshape` define the shapes of the input and output data provided by the arrays `x`, `y`, and `z`, respectively. Each shape parameter is an array of integers with its length equal to the value of `dims`. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter `dims` is 1, then `xshape`, `yshape`, `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. Note that values of shape parameters may differ from physical shapes of arrays `x`, `y`, and `z` if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a NULL task pointer.

vslConvNewTask1D/vslCorrNewTask1D

Creates a new convolution or correlation task descriptor for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslcconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslscorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldcorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslccorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzcorrnewtask1d(task, mode, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslsCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

Description

Each `vslConvNewTask1D/vslCorrNewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)). Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter `dims` is 1. The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

vslConvNewTaskX/vslCorrNewTaskX

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslldconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslccconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslzconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslscorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslldcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslcccorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslzcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslldConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslldCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
```

status	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each vslConvNewTaskX/vslCorrNewTaskX constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

Unlike [vslConvNewTask](#)/[vslCorrNewTask](#), these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the vslConvNewTaskX/vslCorrNewTaskX constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see [vslConvDeleteTask](#)/[vslCorrDeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

The stride parameter *xstride* specifies the physical location of the input data in the array *x*. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is *s*, then only every *s*th element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

vslConvNewTaskX1D/vslCorrNewTaskX1D

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslcconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

```

status = vslscorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslccorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)

```

C:

```

status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);

```

Description

Each `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter `dims` is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see [vslConvDeleteTask/vslCorrDeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

The `stride parameters` `xstride` specifies the physical location of the input data in the array `x` and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every `s`th element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

Task Editors

Task editors in convolution and correlation API of Intel MKL are routines intended for setting up or changing the following task parameters (see [Table "Convolution and Correlation Task Parameters"](#)):

- *mode*
- *internal_precision*
- *start*
- *decimation*

For setting up or changing each of the above parameters, a separate routine exists.

NOTE Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

The work data computed during the last commitment process may become invalid with respect to new parameter settings. That is why after applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and goes through the full commitment process again during the next execution or copy operation. For more information on task commitment, see the [Introduction to Convolution and Correlation](#).

[Table "Task Editors"](#) lists available task editors.

Task Editors

Routine	Description
<code>vslConvSetMode/vslCorrSetMode</code>	Changes the value of the parameter <i>mode</i> for the operation of convolution or correlation.
<code>vslConvSetInternalPrecision/ vslCorrSetInternalPrecision</code>	Changes the value of the parameter <i>internal_precision</i> for the operation of convolution or correlation.
<code>vslConvSetStart/vslCorrSetStart</code>	Sets the value of the parameter <i>start</i> for the operation of convolution or correlation.
<code>vslConvSetDecimation/ vslCorrSetDecimation</code>	Sets the value of the parameter <i>decimation</i> for the operation of convolution or correlation.

NOTE You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

`vslConvSetMode/vslCorrSetMode`

*Changes the value of the parameter *mode* in the convolution or correlation task descriptor.*

Syntax

Fortran:

```
status = vslconvsetmode(task, newmode)
status = vslcorrsetmode(task, newmode)
```

C:

```
status = vslConvSetMode(task, newmode);
status = vslCorrSetMode(task, newmode);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetmode INTEGER*4 task(2) for vslcorrsetmode	Pointer to the task descriptor.
	Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetmode TYPE(VSL_CORR_TASK) for vslcorrsetmode C: VSLConvTaskPtr for vslConvSetMode VSLCorrTaskPtr for vslCorrSetMode	
<i>newmode</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	New value of the parameter mode.

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.f90` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

Values of `mode` parameter

Value	Purpose
<code>VSL_CONV_MODE_FFT</code>	Compute convolution by using fast Fourier transform.
<code>VSL_CORR_MODE_FFT</code>	Compute correlation by using fast Fourier transform.

Value	Purpose
VSL_CONV_MODE_DIRECT	Compute convolution directly.
VSL_CORR_MODE_DIRECT	Compute correlation directly.
VSL_CONV_MODE_AUTO	Automatically choose direct or Fourier mode for convolution.
VSL_CORR_MODE_AUTO	Automatically choose direct or Fourier mode for correlation.

vslConvSetInternalPrecision/vslCorrSetInternalPrecision

*Changes the value of the parameter
internal_precision in the convolution or correlation
task descriptor.*

Syntax

Fortran:

```
status = vslconvsetinternalprecision(task, precision)
status = vslcorrsetinternalprecision(task, precision)
```

C:

```
status = vslConvSetInternalPrecision(task, precision);
status = vslCorrSetInternalPrecision(task, precision);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	FORTRAN 77: INTEGER*4 task(2) for vslconvsetinternalprecision n INTEGER*4 task(2) for vslcorrsetinternalprecision n	Pointer to the task descriptor.
	Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetinternalprecision n TYPE(VSL_CORR_TASK) for vslcorrsetinternalprecision n	
	C: VSLConvTaskPtr for vslConvSetInternalPrecision n	

Name	Type	Description
	VSLCorrTaskPtr for vslCorrSetInternalPrecision	
<i>precision</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: const int	New value of the parameter <i>internal_precision</i> .

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the task.

Description

The `vslConvSetInternalPrecision/vslCorrSetInternalPrecision` routine changes the value of the parameter *internal_precision* for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for *internal_precision* is assigned by a task constructor and set to either "single" or "double" according to the particular flavor of the constructor used.

Changing the *internal_precision* can be useful if the default setting of this parameter was "single" but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the *internal_precision* input parameter are as follows:

Values of *internal_precision* Parameter

Value	Purpose
<code>VSL_CONV_PRECISION_SINGLE</code>	Compute convolution with single precision.
<code>VSL_CORR_PRECISION_SINGLE</code>	Compute correlation with single precision.
<code>VSL_CONV_PRECISION_DOUBLE</code>	Compute convolution with double precision.
<code>VSL_CORR_PRECISION_DOUBLE</code>	Compute correlation with double precision.

`vslConvSetStart/vslCorrSetStart`

Changes the value of the parameter *start* in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetstart(task, start)
status = vslcorrsetstart(task, start)
```

C:

```
status = vslConvSetStart(task, start);
```

```
status = vslCorrSetStart(task, start);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetstart INTEGER*4 task(2) for vslcorrsetstart	Pointer to the task descriptor.
<i>start</i>	Fortran 90: TYPE(VSL_CONV_TASK) for vslconvsetstart TYPE(VSL_CORR_TASK) for vslcorrsetstart	
	C: VSLConvTaskPtr for vslConvSetStart VSLCorrTaskPtr for vslCorrSetStart	
<i>start</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*)	New value of the parameter <i>start</i> .
	C: const int []	

Output Parameters

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER	Current status of the task.
	C: int	

Description

The `vslConvSetStart/vslCorrSetStart` routine sets the value of the parameter *start* for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, *start* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *start* is undefined and this parameter is not used. Therefore the only way to set and use the *start* parameter is via assigning it some value by one of the `vslConvSetStart/vslCorrSetStart` routines.

vslConvSetDecimation/vslCorrSetDecimation

Changes the value of the parameter `decimation` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetdecimation(task, decimation)
status = vslcorrsetdecimation(task, decimation)
```

C:

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<code>task</code>	FORTRAN 77: INTEGER*4 task(2) for vslconvsetdecimation INTEGER*4 task(2) for vslcorrsetdecimation	Pointer to the task descriptor.
Fortran 90:		
	TYPE(VSL_CONV_TASK) for vslconvsetdecimation TYPE(VSL_CORR_TASK) for vslcorrsetdecimation	
C:	VSLConvTaskPtr for vslConvSetDecimation VSLCorrTaskPtr for vslCorrSetDecimation	
<code>decimatio</code> <code>n</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER, DIMENSION (*) C: const int[]	New value of the parameter <code>decimation</code> .

Output Parameters

Name	Type	Description
<code>status</code>	FORTRAN 77: INTEGER Fortran 90: INTEGER	Current status of the task.

Name	Type	Description
C: int		

Description

The routine sets the value of the parameter *decimation* for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if *decimation* = *d* > 1, only every *d*-th element of the mathematical result is written to the output array *z*. In a multidimensional case, *decimation* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Therefore the only way to set and use the *decimation* parameter is via assigning it some value by one of the `vslSetDecimation` routines.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the user data supplied for input vectors.

After you create and adjust a task, you can execute it multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL provides the following forms of convolution/correlation execution routines:

- **General form** executors that use the task descriptor created by the general form constructor and expect to get two source data arrays *x* and *y* on input
- **X-form** executors that use the task descriptor created by the X-form constructor and expect to get only one source data array *y* on input because the first array *x* has been already specified on the construction stage

When the task is executed for the first time, the execution routine includes a task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

Each execution routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE You can use the `NULL` task pointer in calls to execution routines. In this case, the routine is terminated and no system crash occurs.

If the task is executed successfully, the execution routine returns the zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`
- if the task descriptor is corrupted
- if calculation has failed for some other reason.

NOTE Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Task Execution Routines

Routine	Description
<code>vslConvExec/vslCorrExec</code>	Computes convolution or correlation for a multidimensional case.
<code>vslConvExec1D/vslCorrExec1D</code>	Computes convolution or correlation for a one-dimensional case.
<code>vslConvExecX/vslCorrExecX</code>	Computes convolution or correlation as X-form for a multidimensional case.
<code>vslConvExecX1D/vslCorrExecX1D</code>	Computes convolution or correlation as X-form for a one-dimensional case.

`vslConvExec/vslCorrExec`

Computes convolution or correlation for multidimensional case.

Syntax

Fortran:

```
status = vslsconvexec(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);
```

status	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExec/vslCorrExec` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask/vslCorrNewTask` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

The stride parameters `xstride`, `ystride`, and `zstride` specify the physical location of the input and output data in the arrays `x`, `y`, and `z`, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `zstride` is `s`, then only every `s`th element of the array `z` will be used to store the output data. The stride value must be positive or negative but not zero.

vslConvExec1D/vslCorrExec1D

Computes convolution or correlation for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec1d(task, x, xstride, y, ystride, z, zstride)
```

C:

```

Description

Each of the `vslConvExec1D/vslCorrExec1D` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter `dims` is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask1D/vslCorrNewTask1D` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

`vslConvExecX/vslCorrExecX`

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexecx(task, y, ystride, z, zstride)
status = vsldconvexecx(task, y, ystride, z, zstride)
status = vslcconvexecx(task, y, ystride, z, zstride)
status = vslzconvexecx(task, y, ystride, z, zstride)
status = vslscorrexecx(task, y, ystride, z, zstride)
status = vslldcorrexecx(task, y, ystride, z, zstride)
status = vslccorrexecx(task, y, ystride, z, zstride)
status = vslzcorrexecx(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslcConvExecX(task, y, ystride, z, zstride);
status = vslzConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vslcCorrExecX(task, y, ystride, z, zstride);
status = vslzCorrExecX(task, y, ystride, z, zstride);
status = vslldCorrExecX(task, y, ystride, z, zstride);
```

<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExecX/vslCorrExecX` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array `x`.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX/vslCorrNewTaskX` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

vslConvExecX1D/vslCorrExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexecx1d(task, y, ystride, z, zstride)
```

```

status = vslsconvexecx1d(task, y, ystride, z, zstride)
status = vslcconvexecx1d(task, y, ystride, z, zstride)
status = vslzconvexecx1d(task, y, ystride, z, zstride)

<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExecX1D/vslCorrExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

vslConvDeleteTask/vslCorrDeleteTask

Destroys the task object and frees the memory.

Syntax

Fortran:

```
errcode = vslconvdeletetask(task)
errcode = vslcorrdeletetask(task)
```

C:

```
errcode = vslConvDeleteTask(task);
errcode = vslCorrDeleteTask(task);
```

Include Files

- **Fortran:** mkl.fi
- **Fortran 90:** mkl_vsl.f90
- **C:** mkl.h

Input Parameters

Name	Type	Description
task	FORTRAN 77: INTEGER*4 task(2) for vslconvdeletetask INTEGER*4 task(2) for vslcorrdeletetask Fortran 90: TYPE(VSL_CONV_TASK) for vslconvdeletetask TYPE(VSL_CORR_TASK) for vslcorrdeletetask C: VSLConvTaskPtr* for vslConvDeleteTask VSLCorrTaskPtr* for vslCorrDeleteTask	Pointer to the task descriptor.

Output Parameters

Name	Type	Description
errcode	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Contains 0 if the task object is deleted successfully. Contains an error code if an error occurred.

Description

The `vslConvDeleteTask/vslCorrvDeleteTask` routine deletes the task descriptor object and frees any working memory and the memory allocated for the data structure. The task pointer is set to `NULL`.

Note that if the `vslConvDeleteTask/vslCorrvDeleteTask` routine does not delete the task successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine terminates with no system crash.

Task Copy

The routines are designed for copying convolution and correlation task descriptors.

vslConvCopyTask/vslCorrCopyTask

Copies a descriptor for convolution or correlation task.

Syntax

Fortran:

```
status = vslconvcopytask(newtask, srctask)
```

```
status = vslcorrcopytask(newtask, srctask)
```

C:

```
status = vslConvCopyTask(newtask, srctask);
status = vslCorrCopyTask(newtask, srctask);
```

Include Files

- Fortran: mkl.fi
- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
srctask	FORTRAN 77: INTEGER*4 srctask(2) for vslconvcopytask INTEGER*4 srctask(2) for vslcorrcopytask	Pointer to the source task descriptor.

Fortran 90:

vslconvcopytask

TYPE(VSL_CORR_TASK) for
vslcorrcopytask
```

C: const VSLConvTaskPtr for
vslConvCopyTask

```
const VSLCorrTaskPtr for
vslCorrCopyTask
```

Output Parameters

Name	Type	Description
newtask	FORTRAN 77: INTEGER*4 srctask(2) for vslconvcopytask INTEGER*4 srctask(2) for vslcorrcopytask	Pointer to the new task descriptor.

Fortran 90:

```
TYPE(VSL_CONV_TASK) for
vslconvcopytask

TYPE(VSL_CORR_TASK) for
vslcorrcopytask
```

C: VSLConvTaskPtr* for
vslConvCopyTask

```
VSLCorrTaskPtr* for
vslCorrCopyTask
```

Name	Type	Description
<i>status</i>	FORTRAN 77: INTEGER Fortran 90: INTEGER C: int	Current status of the source task.

Description

If a task object *srctask* already exists, you can use an appropriate `vslConvCopyTask/vslCorrCopyTask` routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see [Introduction to Convolution and Correlation](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a NULL pointer instead of a reference to a new task object.

Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single-threaded and multithreaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL* library. The functions assume single-threaded calculations and can be used with C or C++ compilers.

Function `scond1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int scond1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task,VSL_CONV_MODE_DIRECT,nh,nx,ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h,inch, x,incx, y,incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Function `sconf1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    int init,
    float h[], int inc1h,
    float x[], int inc1x, int inc2x,
    float y[], int inc1y, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)

{
    int status;
    /* assume that aux1!=0 and naux1 is big enough */
    VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;
    if (init != 0)
        /* initialization: */
        status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
            nh,nx,ny, h,inc1h);
    if (init == 0) {
        /* calculations: */
        int i;
        vslConvSetStart(*task, &iy0);
        for (i=0; i<m; i++) {
            float* xi = &x[inc2x * i];
            float* yi = &y[inc2y * i];
            /* task is implicitly committed at i==0 */
            status = vslsConvExecX1D(*task, xi, inc1x, yi, inc1y);
        };
    };
    vslConvDeleteTask(task);
    return status;
}
```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If $m>1$, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create m copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code in this case may look as follows:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    ...
    vslConvSetStart(*task, &iy0);
    ...
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i], *task);
    ...
}
```

Then, m threads may be started to execute different copies of the task:

```
...
float* xi = &x[inc2x * i];
float* yi = &y[inc2y * i];
ss[i]=vslsConvExecX1D(tasks[i], xi, inc1x, yi, inc1y);
...
```

And finally, after all threads have finished the calculations, overall status should be collected from all task objects. The following code signals the first error found, if any:

```
...
for (i=0; i<m; i++) {
    status = ss[i];
    if (status != 0) /* 0 means "OK" */
        break;
}
return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. That is why different threads must use different copies of the task.

Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbf{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbf{Z} = \{0, \pm 1, \pm 2, \dots\}$	The set of integer numbers.
$\mathbf{Z}^N = \mathbf{Z} \times \dots \times \mathbf{Z}$	The set of N -dimensional series of integer numbers.
$p = (p_1, \dots, p_N) \in \mathbf{Z}^N$	N -dimensional series of integers.
$u: \mathbf{Z}^N \rightarrow \mathbf{R}$	Function u with arguments from \mathbf{Z}^N and values from \mathbf{R} .
$u(p) = u(p_1, \dots, p_N)$	The value of the function u for the argument (p_1, \dots, p_N) .

$$\begin{aligned} w &= u * v \\ w &= u \bullet v \end{aligned}$$

Function w is the convolution of the functions u, v .
 Function w is the correlation of the functions u, v .

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1, \dots, N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1, \dots, N$
- series $r = \sup\{p, q\}$ is defined as $r^n = \max\{p^n, q^n\}$ for every $n=1, \dots, N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1, \dots, N$
- inequality $p \leq q$ means that $p^n \leq q^n$ for every $n=1, \dots, N$.

A function $u(p)$ is called a finite function if there exist series $P^{\min}, P^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$P^{\min} \leq p \leq P^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series $P^{\min}, P^{\max}, Q^{\min}, Q^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0 \text{ implies } P^{\min} \leq p \leq P^{\max}.$$

$$v(q) \neq 0 \text{ implies } Q^{\min} \leq q \leq Q^{\max}.$$

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u * v$ is the convolution of u and v , then:

$$w(r) \neq 0 \text{ implies } R^{\min} \leq r \leq R^{\max},$$

where $R^{\min} = P^{\min} + Q^{\min}$ and $R^{\max} = P^{\max} + Q^{\max}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$$w(r) = \sum u(t) \cdot v(r-t) \text{ is the sum for all } t \in \mathbf{Z}^N \text{ such that } T^{\min} \leq t \leq T^{\max},$$

where $T^{\min} = \sup\{P^{\min}, r - Q^{\max}\}$ and $T^{\max} = \inf\{P^{\max}, r - Q^{\min}\}$.

Linear Correlation

If function $w = u \bullet v$ is the correlation of u and v , then:

$$w(r) \neq 0 \text{ implies } R^{\min} \leq r \leq R^{\max},$$

where $R^{\min} = Q^{\min} - P^{\max}$ and $R^{\max} = Q^{\max} - P^{\min}$.

If $R^{\min} \leq r \leq R^{\max}$, then:

$$w(r) = \sum u(t) \cdot v(r+t) \text{ is the sum for all } t \in \mathbf{Z}^N \text{ such that } T^{\min} \leq t \leq T^{\max},$$

where $T^{\min} = \sup\{P^{\min}, Q^{\min} - r\}$ and $T^{\max} = \inf\{P^{\max}, Q^{\max} - r\}$.

Representation of the functions u, v, w as the input/output data for the Intel MKL convolution and correlation functions is described in the [Data Allocation](#) section below.

Data Allocation

This section explains the relation between:

- mathematical finite functions u, v, w introduced in the section [Mathematical Notation and Definitions](#);
- multi-dimensional input and output data vectors representing the functions u, v, w ;

- arrays u , v , w used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays x , y , z
- Shape arrays $xshape$, $yshape$, $zshape$
- Strides within arrays $xstride$, $ystride$, $zstride$
- Parameters $start$, $decimation$

Finite Functions and Data Vectors

The finite functions $u(p)$, $v(q)$, and $w(r)$ introduced above are represented as multi-dimensional vectors of input and output data:

```
inputu(i1, ..., idims) for u(p1, ..., pN)
inputv(j1, ..., jdims) for v(q1, ..., qN)
output(k1, ..., kdims) for w(r1, ..., rN).
```

Parameter $dims$ represents the number of dimensions and is equal to N.

The parameters $xshape$, $yshape$, and $zshape$ define the shapes of input/output vectors:

```
inputu(i1, ..., idims) is defined if 1 ≤ in ≤ xshape(n) for every n=1, ..., dims
inputv(j1, ..., jdims) is defined if 1 ≤ jn ≤ yshape(n) for every n=1, ..., dims
output(k1, ..., kdims) is defined if 1 ≤ kn ≤ zshape(n) for every n=1, ..., dims.
```

Relation between the input vectors and the functions u and v is defined by the following formulas:

```
inputu(i1, ..., idims) = u(p1, ..., pN), where pn = Pnmin + (in-1) for every n
inputv(j1, ..., jdims) = v(q1, ..., qN), where qn=Qnmin + (jn-1) for every n.
```

The relation between the output vector and the function $w(r)$ is similar (but only in the case when parameters $start$ and $decimation$ are not defined):

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn=Rnmin + (kn-1) for every n.
```

If the parameter $start$ is defined, it must belong to the interval $R_n^{min} ≤ start(n) ≤ R_n^{max}$. If defined, the $start$ parameter replaces R^{min} in the formula:

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn=start(n) + (kn-1)
```

If the parameter $decimation$ is defined, it changes the relation according to the following formula:

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn= Rnmin + (kn-1)*decimation(n)
```

If both parameters $start$ and $decimation$ are defined, the formula is as follows:

```
output(k1, ..., kdims) = w(r1, ..., rN), where rn=start(n) + (kn-1)*decimation(n)
```

The convolution and correlation software checks the values of $zshape$, $start$, and $decimation$ during task commitment. If r_n exceeds R_n^{max} for some $k_n, n=1, ..., dims$, an error is raised.

Allocation of Data Vectors

Both parameter arrays x and y contain input data vectors in memory, while array z is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters x , y , and z , you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays x , y , and z is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbb{Z}^N$, one-dimensional indices $e, f, g \in \mathbb{Z}$ are defined such that:

```
inputu(i1, ..., idims) is allocated at x(e)
inputv(j1, ..., jdims) is allocated at y(f)
output(k1, ..., kdims) is allocated at z(g).
```

The indices e , f , and g are defined as follows:

$$\begin{aligned} e &= 1 + \sum x\text{stride}(n) \cdot dx(n) \quad (\text{the sum is for all } n=1, \dots, \text{dims}) \\ f &= 1 + \sum y\text{stride}(n) \cdot dy(n) \quad (\text{the sum is for all } n=1, \dots, \text{dims}) \\ g &= 1 + \sum z\text{stride}(n) \cdot dz(n) \quad (\text{the sum is for all } n=1, \dots, \text{dims}) \end{aligned}$$

The distances $dx(n)$, $dy(n)$, and $dz(n)$ depend on the signum of the stride:

$$\begin{aligned} dx(n) &= i_n - 1 \text{ if } x\text{stride}(n) > 0, \text{ or } dx(n) = i_n - x\text{shape}(n) \text{ if } x\text{stride}(n) < 0 \\ dy(n) &= j_n - 1 \text{ if } y\text{stride}(n) > 0, \text{ or } dy(n) = j_n - y\text{shape}(n) \text{ if } y\text{stride}(n) < 0 \\ dz(n) &= k_n - 1 \text{ if } z\text{stride}(n) > 0, \text{ or } dz(n) = k_n - z\text{shape}(n) \text{ if } z\text{stride}(n) < 0 \end{aligned}$$

The definitions of indices e , f , and g assume that indexes for arrays x , y , and z are started from unity:

$x(e)$ is defined for $e=1, \dots, \text{length}(x)$
 $y(f)$ is defined for $f=1, \dots, \text{length}(y)$
 $z(g)$ is defined for $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array z for one-dimensional and two-dimensional cases.

One-dimensional case. If $\text{dims}=1$, then $z\text{shape}$ is the number of the output values to be stored in the array z . The actual length of array z may be greater than $z\text{shape}$ elements.

If $z\text{stride} > 1$, output values are stored with the stride: $\text{output}(1)$ is stored to $z(1)$, $\text{output}(2)$ is stored to $z(1+z\text{stride})$, and so on. Hence, the actual length of z must be at least $1+z\text{stride} * (z\text{shape}-1)$ elements or more.

If $z\text{stride} < 0$, it still defines the stride between elements of array z . However, the order of the used elements is the opposite. For the k -th output value, $\text{output}(k)$ is stored in $z(1+|z\text{stride}| * (z\text{shape}-k))$, where $|z\text{stride}|$ is the absolute value of $z\text{stride}$. The actual length of the array z must be at least $1+|z\text{stride}| * (z\text{shape} - 1)$ elements.

Two-dimensional case. If $\text{dims}=2$, the output data is a two-dimensional matrix. The value $z\text{stride}(1)$ defines the stride inside matrix columns, that is, the stride between the $\text{output}(k_1, k_2)$ and $\text{output}(k_1+1, k_2)$ for every pair of indices k_1, k_2 . On the other hand, $z\text{stride}(2)$ defines the stride between columns, that is, the stride between $\text{output}(k_1, k_2)$ and $\text{output}(k_1, k_2+1)$.

If $z\text{stride}(2)$ is greater than $z\text{shape}(1)$, this causes sparse allocation of columns. If the value of $z\text{stride}(2)$ is smaller than $z\text{shape}(1)$, this may result in the transposition of the output matrix. For example, if $z\text{shape} = (2, 3)$, you can define $z\text{stride} = (3, 1)$ to allocate output values like transposed matrix of the shape 3×2 .

Whether $z\text{stride}$ assumes this kind of transformations or not, you need to ensure that different elements $\text{output}(k_1, \dots, k_{\text{dims}})$ will be stored in different locations $z(g)$.

VSL Summary Statistics

The VSL Summary Statistics domain comprises a set of routines that compute basic statistical estimates for single and double precision multi-dimensional datasets.

See the definition of the supported operations in the [Mathematical Notation and Definitions](#) section.

The VSL Summary Statistics routines calculate:

- raw and central moments up to the fourth order
- skewness and excess kurtosis (further referred to as *kurtosis* for brevity)
- variation coefficient
- quantiles and order statistics
- minimum and maximum
- variance-covariance/correlation matrix
- pooled/group variance-covariance matrix and mean
- partial variance-covariance/correlation matrix
- robust estimators for variance-covariance matrix and mean in presence of outliers

The library also contains functions to perform the following tasks:

- Detect outliers in datasets
- Support missing values in datasets
- Parameterize correlation matrices
- Compute quantiles for streaming data

You can access the VSL Summary Statistics routines through the Fortran 90 and C89 language interfaces. You can also use the C89 interface with later versions of the C/C++, or Fortran 90 interface with programs written in Fortran 95.

For users of the C/C++ and Fortran languages, Intel MKL provides the `mkl_vsl.h`, `mkl_vsl.f90`, and `mkl_vsl.f77` header files. All the header files are in the directory

```
$(MKL)/include
```

See more details about the Fortran header in the [Random Number Generators](#) section of this chapter.

You can find examples that demonstrate calculation of the VSL Summary Statistics estimates in the following directories:

```
$(MKL)/examples/vs1c
$(MKL)/examples/vs1f
```

The VSL Summary Statistics API is implemented through task objects, or tasks. A task object is a data structure, or a descriptor, holding parameters that determine a specific VSL Summary Statistics operation. For example, such parameters may be precision, dimensions of user data, the matrix of the observations, or shapes of data arrays.

All the VSL Summary Statistics routines process a task object as follows:

1. Create a task.
2. Modify settings of the task parameters.
3. Compute statistical estimates.
4. Destroy the task.

The VSL Summary Statistics functions fall into the following categories:

[Task Constructors](#) - routines that create a new task object descriptor and set up most common parameters (dimension, number of observations, and matrix of the observations).

[Task Editors](#) - routines that can set or modify some parameter settings in the existing task descriptor.

[Task Computation Routine](#) - a routine that computes specified statistical estimates.

[Task Destructor](#) - a routine that deletes the task object and frees the memory.

A VSL Summary Statistics task object contains a series of pointers to the input and output data arrays. You can read and modify the datasets and estimates at any time but you should allocate and release memory for such data.

See detailed information on the algorithms, API, and their usage in the *Intel® MKL Summary Statistics Library Application Notes* on the Intel® MKL web page.

Naming Conventions

The names of the Fortran routines in the VSL Summary Statistics are in lowercase (`vslsseditquantiles`), while the names of types and constants are in uppercase. The names are not case-sensitive.

In C, the names of the routines, types, and constants are case-sensitive and can be lowercase and uppercase (`vslSSSEditQuantiles`).

The names of routines have the following structure:

`vsl[datatype] SS<base name>` for the C interface

`vsl[datatype] ss<base name>` for the Fortran interface

where

- `vsl` is a prefix indicating that the routine belongs to the Vector Statistical Library of Intel MKL.
- `[datatype]` specifies the type of the input and/or output data and can be `s` (single precision real type), `d` (double precision real type), or `i` (integer type).
- `SS/ss` indicates that the routine is intended for calculations of the VSL Summary Statistics estimates.
- `<base name>` specifies a particular functionality that the routine is designed for, for example, `NewTask`, `Compute`, `DeleteTask`.

NOTE The VSL Summary Statistics routine `vslDeleteTask` for deletion of the task is independent of the data type and its name omits the `[datatype]` field.

Data Types

The VSL Summary Statistics routines use the following data types for the calculations:

Type	Data Object
Fortran 90: <code>TYPE(VSL_SS_TASK)</code>	Pointer to a VSL Summary Statistics task
C: <code>VSLSSTaskPtr</code>	
Fortran 90: <code>REAL(KIND=4)</code>	Input/output user data in single precision
C: <code>float</code>	
Fortran 90: <code>REAL(KIND=8)</code>	Input/output user data in double precision
C: <code>double</code>	
Fortran 90: <code>INTEGER or INTEGER(KIND=8)</code>	Other data
C: <code>MKL_INT or long long</code>	

NOTE The actual size of the generic integer type is platform-specific and can be 32 or 64 bits in length. Before you compile your application, set an appropriate size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL User's Guide*.

Parameters

The basic parameters in the task descriptor (addresses of dimensions, number of observations, and datasets) are assigned values when the task editors create or modify the task object. Other parameters are determined by the specific task and changed by the task editors.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error is detected, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names defined in the respective header files. For the C/C++ interface, these names are defined as macros via the `#define` statements, and for the Fortran interface as integer constants via the `PARAMETER` operators.

If no error is detected, the function returns the `VSL_STATUS_OK` code, which is defined as zero:

C/C++:	<code>#define VSL_STATUS_OK 0</code>
F90/F95:	<code>INTEGER, PARAMETER::VSL_STATUS_OK = 0</code>

In the case of an error, the function returns a non-zero error code that specifies the origin of the failure. The header files for both C/C++ and Fortran languages define the following status codes for the VSL Summary Statistics error codes:

VSL Summary Statistics Status Codes

Status Code	Description
<code>VSL_STATUS_OK</code>	Operation is successfully completed.
<code>VSL_SS_ERROR_ALLOCATION_FAILURE</code>	Memory allocation has failed.
<code>VSL_SS_ERROR_BAD_DIMEN</code>	Dimension value is invalid.
<code>VSL_SS_ERROR_BAD_OBSERV_N</code>	Invalid number (zero or negative) of observations was obtained.
<code>VSL_SS_ERROR_STORAGE_NOT_SUPPORTED</code>	Storage format is not supported.
<code>VSL_SS_ERROR_BAD_INDC_ADDR</code>	Array of indices is not defined.
<code>VSL_SS_ERROR_BAD_WEIGHTS</code>	Array of weights contains negative values.
<code>VSL_SS_ERROR_BAD_MEAN_ADDR</code>	Array of means is not defined.
<code>VSL_SS_ERROR_BAD_2R_MOM_ADDR</code>	Array of the second order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_3R_MOM_ADDR</code>	Array of the third order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_4R_MOM_ADDR</code>	Array of the fourth order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_2C_MOM_ADDR</code>	Array of the second order central moments is not defined.
<code>VSL_SS_ERROR_BAD_3C_MOM_ADDR</code>	Array of the third order central moments is not defined.
<code>VSL_SS_ERROR_BAD_4C_MOM_ADDR</code>	Array of the fourth order central moments is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_KURTOSIS_ADDR	Array of kurtosis values is not defined.
VSL_SS_ERROR_BAD_SKEWNESS_ADDR	Array of skewness values is not defined.
VSL_SS_ERROR_BAD_MIN_ADDR	Array of minimum values is not defined.
VSL_SS_ERROR_BAD_MAX_ADDR	Array of maximum values is not defined.
VSL_SS_ERROR_BAD_VARIATION_ADDR	Array of variation coefficients is not defined.
VSL_SS_ERROR_BAD_COV_ADDR	Covariance matrix is not defined.
VSL_SS_ERROR_BAD_COR_ADDR	Correlation matrix is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER_ADDR	Array of quantile orders is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER	Quantile order value is invalid.
VSL_SS_ERROR_BAD_QUANT_ADDR	Array of quantiles is not defined.
VSL_SS_ERROR_BAD_ORDER_STATS_ADDR	Array of order statistics is not defined.
VSL_SS_ERROR_MOMORDER_NOT_SUPPORTED	Moment of requested order is not supported.
VSL_SS_NOT_FULL_RANK_MATRIX	Correlation matrix is not of full rank.
VSL_SS_ERROR_ALL_OBSERVS_OUTLIERS	All observations are outliers. (At least one observation must not be an outlier.)
VSL_SS_ERROR_BAD_ROBUST_COV_ADDR	Robust covariance matrix is not defined.
VSL_SS_ERROR_BAD_ROBUST_MEAN_ADDR	Array of robust means is not defined.
VSL_SS_ERROR_METHOD_NOT_SUPPORTED	Requested method is not supported.
VSL_SS_ERROR_NULL_TASK_DESCRIPTOR	Task descriptor is null.
VSL_SS_ERROR_BAD_OBSERV_ADDR	Dataset matrix is not defined.
VSL_SS_ERROR_BAD_ACCUM_WEIGHT_ADDR	Pointer to the variable that holds the value of accumulated weight is not defined.
VSL_SS_ERROR_SINGULAR_COV	Covariance matrix is singular.
VSL_SS_ERROR_BAD_POOLED_COV_ADDR	Pooled covariance matrix is not defined.
VSL_SS_ERROR_BAD_POOLED_MEAN_ADDR	Array of pooled means is not defined.
VSL_SS_ERROR_BAD_GROUP_COV_ADDR	Group covariance matrix is not defined.
VSL_SS_ERROR_BAD_GROUP_MEAN_ADDR	Array of group means is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC_ADDR	Array of group indices is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC	Group indices have improper values.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_ADDR	Array of parameters for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_N_ADDR	Pointer to size of the parameter array for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_WEIGHTS_ADDR	Output of the outlier detection algorithm is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_ADDR	Array of parameters of the robust covariance estimation algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_N_ADDR	Pointer to the number of parameters of the algorithm for robust covariance is not defined.
VSL_SS_ERROR_BAD_STORAGE_ADDR	Pointer to the variable that holds the storage format is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX_ADDR	Array that encodes sub-components of a random vector for the partial covariance algorithm is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX	Array that encodes sub-components of a random vector for partial covariance has improper values.
VSL_SS_ERROR_BAD_PARTIAL_COV_ADDR	Partial covariance matrix is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COR_ADDR	Partial correlation matrix is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_ADDR	Array of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_N_ADDR	Pointer to number of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_BAD_PARAMS_N	Size of the parameter array of the Multiple Imputation method is invalid.
VSL_SS_ERROR_BAD_MI_PARAMS	Parameters of the Multiple Imputation method are invalid.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_N_ADDR	Pointer to the number of initial estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_ADDR	Array of initial estimates for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_ADDR	Array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N_ADDR	Pointer to the size of the array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N_ADDR	Pointer to the number of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_ADDR	Array of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N	Invalid size of the array of simulated values in the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N	Invalid size of an array to hold parameter estimates obtained using the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_OUTPUT_PARAMS	Array of output parameters in the Multiple Imputation method is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_MI_PRIOR_N_ADDR	Pointer to the number of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_ADDR	Array of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_MISSING_VALS_N	Invalid number of missing values was obtained.
VSL_SS_SEMIDEFINITE_COR	Correlation matrix passed into the parameterization function is semi-definite.
VSL_SS_ERROR_BAD_PARAMTR_COR_ADDR	Correlation matrix to be parameterized is not defined.
VSL_SS_ERROR_BAD_COR	All eigenvalues of the correlation matrix to be parameterized are non-positive.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N_ADDR	Pointer to the number of parameters for the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_ADDR	Array of parameters of the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N	Invalid number of parameters of the quantile computation algorithm for streaming data has been obtained.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS	Invalid parameters of the quantile computation algorithm for streaming data have been passed.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER_ADDR	Array of the quantile orders for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER	Invalid quantile order for streaming data is defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ADDR	Array of quantiles for streaming data is not defined.

Routines for robust covariance estimation, outlier detection, partial covariance estimation, multiple imputation, and parameterization of a correlation matrix can return internal error codes that are related to a specific implementation. Such error codes indicate invalid input data or other bugs in the Intel MKL routines other than the VSL Summary Statistics routines.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters.

NOTE If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

vsISSNewTask

Creates and initializes a new summary statistics task descriptor.

Syntax

Fortran:

```
status = vslsssnewtask(task, p, n, xstorage, x, w, indices)
status = vslldssnewtask(task, p, n, xstorage, x, w, indices)
```

C:

```
status = vslsSSNewTask(&task, p, n, xstorage, x, w, indices);
status = vsldSSNewTask(&task, p, n, xstorage, x, w, indices);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
p	Fortran: INTEGER C: MKL_INT	Dimension of the task, number of variables
n	Fortran: INTEGER C: MKL_INT	Number of observations
xstorage	Fortran: INTEGER C: MKL_INT	Storage format of matrix of observations
x	Fortran: REAL(KIND=4) DIMENSION(*) for vslsssnewtask REAL(KIND=8) DIMENSION(*) for vslldssnewtask C: float* for vslsSSNewTask double* for vsldSSNewTask	Matrix of observations
w	Fortran: REAL(KIND=4) DIMENSION(*) for vslsssnewtask REAL(KIND=8) DIMENSION(*) for vslldssnewtask C: float* for vslsSSNewTask double* for vsldSSNewTask	Array of weights of size n. Elements of the arrays are non-negative numbers. If a NULL pointer is passed, each observation is assigned weight equal to 1.
indices	Fortran: INTEGER, DIMENSION(*) C: MKL_INT*	Array of vector components that will be processed. Size of array is p. If a NULL pointer is passed, all components of random vector are processed.

Output Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr*	Descriptor of the task
<i>status</i>	Fortran: INTEGER C: int	Set to <code>VSL_STATUS_OK</code> if the task is created successfully, otherwise a non-zero error code is returned.

Description

Each `vslSSNewTask` constructor routine creates a new summary statistics task descriptor with the user-specified value for a required parameter, dimension of the task. The optional parameters (matrix of observations, its storage format, number of observations, weights of observations, and indices of the random vector components) are set to their default values.

The observations of random p -dimensional vector $\xi = (\xi_1, \dots, \xi_i, \dots, \xi_p)$, which are n vectors of dimension p , are passed as a one-dimensional array x . The parameter `xstorage` defines the storage format of the observations and takes one of the possible values listed in [Table "Storage format of matrix of observations and order statistics"](#).

NOTE Since matrices in Fortran are stored by columns while in C they are stored by rows, initialization of the `xstorage` variable in Fortran is opposite to that in C. Set `xstorage` to `VSL_SS_MATRIX_STORAGE_COLS`, if the dataset is stored as a two-dimensional matrix that consists of p rows and n columns; otherwise, use the `VSL_SS_MATRIX_STORAGE_ROWS` constant.

Storage format of matrix of observations and order statistics

Parameter	Description
<code>VSL_SS_MATRIX_STORAGE_ROWS</code>	The observations of random vector ξ are packed by rows: n data points for the vector component ξ_1 come first, n data points for the vector component ξ_2 come second, and so forth.
<code>VSL_SS_MATRIX_STORAGE_COLS</code>	The observations of random vector ξ are packed by columns: the first p -dimensional observation of the vector ξ comes first, the second p -dimensional observation of the vector comes second, and so forth.

A one-dimensional array w of size n contains non-negative weights assigned to the observations. You can pass a `NULL` array into the constructor. In this case, each observation is assigned the default value of the weight.

You can choose vector components for which you wish to compute statistical estimates. If an element of the vector indices of size p contains 0, the observations that correspond to this component are excluded from the calculations. If you pass the `NULL` value of the parameter into the constructor, statistical estimates for all random variables are computed.

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

Task Editors

Task editors are intended to set up or change the task parameters listed in [Table "Parameters of VSL Summary Statistics Task to Be Initialized or Modified"](#). As an example, to compute the sample mean for a one-dimensional dataset, initialize a variable for the mean value, and pass its address into the task as shown in the example below:

```
#define DIM      1
#define N       1000

int main()
{
    VSLSSTaskPtr task;
    double x[N];
    double mean;
    MKL_INT p, n, xstorage;
    int status;
    /* initialize variables used in the computations of sample mean */
    p = DIM;
    n = N;
    xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
    mean = 0.0;

    /* create task */
    status = vslSSNewTask( &task, &p, &n, &xstorage, x, 0, 0 );

    /* initialize task parameters */
    status = vslSSEditTask( task, VSL_SS_ED_MEAN, &mean );

    /* compute mean using SS fast method */
    status = vslSSCompute(task, VSL_SS_MEAN, VSL_SS_METHOD_FAST );

    /* deallocate task resources */
    status = vslSSDeleteTask( &task );

    return 0;
}
```

Use the single (`vslsssedittask`) or double (`vslsssedittask`) version of an editor, to initialize single or double precision version task parameters, respectively. Use an integer version of an editor (`vslissedittask`) to initialize parameters of the integer type.

[Table "VSL Summary Statistics Task Editors"](#) lists the task editors for VSL Summary Statistics. Each of them initializes and/or modifies a respective group of related parameters.

VSL Summary Statistics Task Editors

Editor	Description
<code>vslSSEditTask</code>	Changes a pointer in the task descriptor.
<code>vslSSEditMoments</code>	Changes pointers to arrays associated with raw and central moments.
<code>vslSSEditCovCor</code>	Changes pointers to arrays associated with covariance and/or correlation matrices.
<code>vslSSEditPartialCovCor</code>	Changes pointers to arrays associated with partial covariance and/or correlation matrices.
<code>vslSSEditQuantiles</code>	Changes pointers to arrays associated with quantile/order statistics calculations.
<code>vslSSEditStreamQuantiles</code>	Changes pointers to arrays for quantile related calculations for streaming data.
<code>vslSSEditPooledCovariance</code>	Changes pointers to arrays associated with algorithms related to a pooled covariance matrix.

Editor	Description
<code>vslSSEditRobustCovariance</code>	Changes pointers to arrays for robust estimation of a covariance matrix and mean.
<code>vslSSEditOutliersDetection</code>	Changes pointers to arrays for detection of outliers.
<code>vslSSEditMissingValues</code>	Changes pointers to arrays associated with the method of supporting missing values in a dataset.
<code>vslSSEditCorParameterization</code>	Changes pointers to arrays associated with the algorithm for parameterization of a correlation matrix.

NOTE You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vsISSEditTask

Modifies address of an input/output parameter in the task descriptor.

Syntax

Fortran:

```
status = vslsssedittask(task, parameter, par_addr)
status = vslsssedittask(task, parameter, par_addr)
status = vslissedittask(task, parameter, par_addr)
```

C:

```
status = vslsSSEditTask(task, parameter, par_addr);
status = vslsSSEditTask(task, parameter, par_addr);
status = vslisSSEditTask(task, parameter, par_addr);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: <code>TYPE(VSL_SS_TASK)</code> C: <code>VSLSTaskPtr</code>	Descriptor of the task
<code>parameter</code>	Fortran: <code>INTEGER</code> C: <code>MKL_INT</code>	Parameter to change
<code>par_addr</code>	Fortran: <code>REAL(KIND=4) DIMENSION(*) for vslssedittask</code> <code>REAL(KIND=8) DIMENSION(*) for vslssedittask</code>	Address of the new parameter

Name	Type	Description
	INTEGER DIMENSION(*) for vslssedittask C: float* for vslsSSEditTask double* for vsldSSEditTask MKL_INT* for vsliSSEditTask	

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditTask` routine replaces the pointer to the parameter stored in the VSL Summary Statistics task descriptor with the `par_addr` pointer. If you pass the NULL pointer to the editor, no changes take place in the task and a corresponding error code is returned. See [Table "Parameters of VSL Summary Statistics Task to Be Initialized or Modified"](#) for the predefined values of the parameter.

Use the single (`vslssedittask`) or double (`vsldssedittask`) version of the editor, to initialize single or double precision version task parameters, respectively. Use an integer version of the editor (`vslssedittask`) to initialize parameters of the integer type.

Parameters of VSL Summary Statistics Task to Be Initialized or Modified

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_DIMEN	i	Address of a variable that holds the task dimension	Required. Positive integer value.
VSL_SS_ED_OBSERV_N	i	Address of a variable that holds the number of observations	Required. Positive integer value.
VSL_SS_ED_OBSERV	d, s	Address of the observation matrix	Required. Provide the matrix containing your observations.
VSL_SS_ED_OBSERV_STORAGE	i	Address of a variable that holds the storage format for the observation matrix	Required. Provide a storage format supported by the library whenever you pass a matrix of observations. ¹
VSL_SS_ED_INDC	i	Address of the array of indices	Optional. Provide this array if you need to process individual components of the random vector. Set entry <i>i</i> of the array to one to include the <i>i</i> th coordinate in the analysis. Set entry <i>i</i> of the array to zero to exclude the <i>i</i> th coordinate from the analysis.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_WEIGHTS	d, s	Address of the array of observation weights	Optional. If the observations have weights different from the default weight (one), set entries of the array to non-negative floating point values.
VSL_SS_ED_MEAN	d, s	Address of the array of means	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_MOM	d, s	Address of an array of raw moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_MOM	d, s	Address of an array of raw moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_MOM	d, s	Address of an array of raw moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2C_MOM	d, s	Address of an array of central moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_3C_MOM	d, s	Address of an array of central moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_4C_MOM	d, s	Address of an array of central moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make

Parameter Value	Type	Purpose	Initialization
			sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_KURTOSIS	d, s	Address of the array of kurtosis estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_SKEWNESS	d, s	Address of the array of skewness estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_MIN	d, s	Address of the array of minimum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_MAX	d, s	Address of the array of maximum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_VARIATION	d, s	Address of the array of variation coefficients	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_COV	d, s	Address of a covariance matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Make sure you also provide an array for the mean.
VSL_SS_ED_COV_STORAGE	i	Address of the variable that holds the storage format for a covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute the covariance matrix. ²
VSL_SS_ED_COR	d, s	Address of a correlation matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. If you

Parameter Value	Type	Purpose	Initialization
			initialize the matrix in non-trivial way, make sure that the main diagonal contains variance values. Also, provide an array for the mean.
VSL_SS_ED_COR_STORAGE	i	Address of the variable that holds the correlation storage format for a correlation matrix	Required. Provide a storage format supported by the library whenever you intend to compute the correlation matrix. ²
VSL_SS_ED_ACCUM_WEIGHT	d, s	Address of the array of size 2 that holds the accumulated weight (sum of weights) in the first position and the sum of weights squared in the second position	Optional. Set the entries of the matrix to meaningful values (typically zero) if you intend to do progressive processing of the dataset or need the sum of weights and sum of squared weights assigned to observations.
VSL_SS_ED_QUANT_ORDER_N	i	Address of the variable that holds the number of quantile orders	Required. Positive integer value. Provide the number of quantile orders whenever you compute quantiles.
VSL_SS_ED_QUANT_ORDER	d, s	Address of the array of quantile orders	Required. Set entries of array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_QUANT_QUANTILE_S	d, s	Address of the array of quantiles	None.
VSL_SS_ED_ORDER_STATS	d, s	Address of the array of order statistics	None.
VSL_SS_ED_GROUP_INDC	i	Address of the array of group indices used in computation of a pooled covariance matrix	Required. Set entry <i>i</i> to integer value <i>k</i> if the observation belongs to group <i>k</i> . Values of <i>k</i> take values in the range [0, <i>g</i> -1], where <i>g</i> is the number of groups.
VSL_SS_ED_POOLED_COV_STORAGE	i	Address of a variable that holds the storage format for a pooled covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute pooled covariance. ²
VSL_SS_ED_POOLED_MEAN	i	Address of an array of pooled means	None.
VSL_SS_ED_POOLED_COV	d, s	Address of pooled covariance matrices	None.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_GROUP_COV_INDC	d, s	Address of an array of indices for which covariance/means should be computed	Optional. Set the k th entry of the array to 1 if you need group covariance and mean for group k ; otherwise set it to zero.
VSL_SS_ED_GROUP_MEANS	i	Address of an array of group means	None.
VSL_SS_ED_GROUP_COV_STOR AGE	d, s	Address of a variable that holds the storage format for a group covariance matrix	Required. Provide a storage format supported by the library whenever you intend to get group covariance. ²
VSL_SS_ED_GROUP_COV	i	Address of group covariance matrices	None.
VSL_SS_ED_ROBUST_COV_STO RAGE	d, s	Address of a variable that holds the storage format for a robust covariance matrix	Required. Provide a storage format supported by the library whenever you compute robust covariance ² .
VSL_SS_ED_ROBUST_COV_PAR AMS_N	i	Address of a variable that holds the number of algorithmic parameters of the method for robust covariance estimation	Required. Set to the number of TBS parameters, <i>VSL_SS_TBS_PARAMS_N</i> .
VSL_SS_ED_ROBUST_COV_PAR AMS	d, s	Address of an array of parameters of the method for robust estimation of a covariance	Required. Set the entries of the array according to the description in EditRobustCovariance .
VSL_SS_ED_ROBUST_MEAN	i	Address of an array of robust means	None.
VSL_SS_ED_ROBUST_COV	d, s	Address of a robust covariance matrix	None.
VSL_SS_ED_OUTLIERS_PARAM S_N	d, s	Address of a variable that holds the number of parameters of the outlier detection method	Required. Set to the number of outlier detection parameters, <i>VSL_SS_BACON_PARAMS_N</i> .
VSL_SS_ED_OUTLIERS_PARAM S	i	Address of an array of algorithmic parameters for the outlier detection method	Required. Set the entries of the array according to the description in EditOutliersDetection .
VSL_SS_ED_OUTLIERS_WEIGHT	d, s	Address of an array of weights assigned to observations by the outlier detection method	None.
VSL_SS_ED_ORDER_STATS_ST ORAGE	d, s	Address of a variable that holds the storage format of an order statistics matrix	Required. Provide a storage format supported by the library whenever you compute a matrix of order statistics. ¹

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_PARTIAL_COV_ID_X	i	Address of an array that encodes subcomponents of a random vector	Required. Set the entries of the array according to the description in EditPartialCovCor .
VSL_SS_ED_PARTIAL_COV	d, s	Address of a partial covariance matrix	None.
VSL_SS_ED_PARTIAL_COV_STORAGE	i	Address of a variable that holds the storage format of a partial covariance matrix	Required. Provide a storage format supported by the library whenever you compute the partial covariance. ²
VSL_SS_ED_PARTIAL_COR	d, s	Address of a partial correlation matrix	None.
VSL_SS_ED_PARTIAL_COR_STORAGE	i	Address of a variable that holds the storage format for a partial correlation matrix	Required. Provide a storage format supported by the library whenever you compute the partial correlation. ²
VSL_SS_ED_MI_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters for the Multiple Imputation method	Required. Set to the number of MI parameters, <i>VSL_SS_MI_PARAMS_SIZE</i> .
VSL_SS_ED_MI_PARAMS	d, s	Address of an array of algorithmic parameters for the Multiple Imputation method	Required. Set entries of the array according to the description in EditMissingValues .
VSL_SS_ED_MI_INIT_ESTIMATES_N	i	Address of a variable that holds the number of initial estimates for the Multiple Imputation method	Optional. Set to $p+p*(p+1)/2$, where p is the task dimension.
VSL_SS_ED_MI_INIT_ESTIMATES	d, s	Address of an array of initial estimates for the Multiple Imputation method	Optional. Set the values of the array according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document on the Intel® MKL web page.
VSL_SS_ED_MI_SIMUL_VALS_N	i	Address of a variable that holds the number of simulated values in the Multiple Imputation method	Optional. Positive integer indicating the number of missing points in the observation matrix.
VSL_SS_ED_MI_SIMUL_VALS	d, s	Address of an array of simulated values in the Multiple Imputation method	None.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_MI_ESTIMATES_N	i	Address of a variable that holds the number of estimates obtained as a result of the Multiple Imputation method	Optional. Positive integer number defined according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document on the Intel® MKL web page.
VSL_SS_ED_MI_ESTIMATES	d, s	Address of an array of estimates obtained as a result of the Multiple Imputation method	None.
VSL_SS_ED_MI_PRIOR_N	i	Address of a variable that holds the number of prior parameters for the Multiple Imputation method	Optional. If you pass a user-defined array of prior parameters, set this parameter to $(p^2+3*p+4)/2$, where p is the task dimension.
VSL_SS_ED_MI_PRIOR	d, s	Address of an array of prior parameters for the Multiple Imputation method	Optional. Set entries of the array of prior parameters according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document on the Intel® MKL web page.
VSL_SS_ED_PARAMTR_COR	d, s	Address of a parameterized correlation matrix	None.
VSL_SS_ED_PARAMTR_COR_ST ORAGE	i	Address of a variable that holds the storage format of a parameterized correlation matrix	Required. Provide a storage format supported by the library whenever you compute the parameterized correlation matrix. ²
VSL_SS_ED_STREAM_QUANT_P ARAMS_N	i	Address of a variable that holds the number of parameters of a quantile computation method for streaming data	Required. Set to the number of quantile computation parameters, <i>VSL_SS_SQUANTS_ZW_PARAMS_N</i> .
VSL_SS_ED_STREAM_QUANT_P ARAMS	d, s	Address of an array of parameters of a quantile computation method for streaming data	Required. Set the entries of the array according to the description in "Computing Quantiles for Streaming Data" in the <i>Intel® MKL Summary Statistics Library Application Notes</i> document on the Intel® MKL web page.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_STREAM_QUANT_O RDER_N	i	Address of a variable that holds the number of quantile orders for streaming data	Required. Positive integer value.
VSL_SS_ED_STREAM_QUANT_O RDER	d, s	Address of an array of quantile orders for streaming data	Required. Set entries of the array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_STREAM_QUANT_Q UANTILES	d, s	Address of an array of quantiles for streaming data	None.

1. See [Table: "Storage format of matrix of observations and order statistics"](#) for storage formats.
2. See [Table: "Storage formats of a variance-covariance/correlation matrix"](#) for storage formats.

vsISSEditMoments

Modifies the pointers to arrays that hold moment estimates.

Syntax

Fortran:

```
status = vslssseditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
status = vsldsseditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
```

C:

```
status = vslsSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
status = vsldSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
mean	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments REAL(KIND=8) DIMENSION(*) for vsldsseditmoments C: float* for vslsSSEditMoments double* for vsldSSEditMoments	Pointer to the array of means
r2m	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments	Pointer to the array of raw moments of the 2 nd order

Name	Type	Description
	<pre>REAL(KIND=8) DIMENSION(*) for vslsseditmoments</pre> <p>C: float* for vslsSSEditMoments double* for vsldSSEditMoments</p>	
<i>r3m</i>	<p>Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments</p> <pre>REAL(KIND=8) DIMENSION(*) for vslsseditmoments</pre> <p>C: float* for vslsSSEditMoments double* for vsldSSEditMoments</p>	Pointer to the array of raw moments of the 3 rd order
<i>r4m</i>	<p>Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments</p> <pre>REAL(KIND=8) DIMENSION(*) for vslsseditmoments</pre> <p>C: float* for vslsSSEditMoments double* for vsldSSEditMoments</p>	Pointer to the array of raw moments of the 4 th order
<i>c2m</i>	<p>Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments</p> <pre>REAL(KIND=8) DIMENSION(*) for vslsseditmoments</pre> <p>C: float* for vslsSSEditMoments double* for vsldSSEditMoments</p>	Pointer to the array of central moments of the 2 nd order
<i>c3m</i>	<p>Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments</p> <pre>REAL(KIND=8) DIMENSION(*) for vslsseditmoments</pre> <p>C: float* for vslsSSEditMoments double* for vsldSSEditMoments</p>	Pointer to the array of central moments of the 3 rd order
<i>c4m</i>	<p>Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditmoments</p> <pre>REAL(KIND=8) DIMENSION(*) for vslsseditmoments</pre> <p>C: float* for vslsSSEditMoments double* for vsldSSEditMoments</p>	Pointer to the array of central moments of the 4 th order

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER	Current status of the task

Name	Type	Description
C:	int	

Description

The `vslSSEditMoments` routine replaces pointers to the arrays that hold estimates of raw and central moments with values passed as corresponding parameters of the routine. If an input parameter is `NULL`, the value of the relevant parameter remains unchanged.

`vslSSEditCovCor`

Modifies the pointers to covariance/correlation parameters.

Syntax

Fortran:

```
status = vslssseditcovcor(task, mean, cov, cov_storage, cor, cor_storage)
status = vsldsseditcovcor(task, mean, cov, cov_storage, cor, cor_storage)
```

C:

```
status = vslsSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
status = vsldSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
task	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
mean	Fortran: REAL(KIND=4) DIMENSION(*) for <code>vslssseditcovcor</code> REAL(KIND=8) DIMENSION(*) for <code>vsldsseditcovcor</code> C: float* for <code>vslsSSEditCovCor</code> double* for <code>vsldSSEditCovCor</code>	Pointer to the array of means
cov	Fortran: REAL(KIND=4) DIMENSION(*) for <code>vslssseditcovcor</code> REAL(KIND=8) DIMENSION(*) for <code>vsldsseditcovcor</code> C: float* for <code>vslsSSEditCovCor</code> double* for <code>vsldSSEditCovCor</code>	Pointer to a covariance matrix
<code>cov_storage</code>	Fortran: INTEGER	Pointer to the storage format of the covariance matrix

Name	Type	Description
<i>cor</i>	C: MKL_INT*	
	Fortran: REAL(KIND=4) DIMENSION(*) for vsLSSSEditCovCor REAL(KIND=8) DIMENSION(*) for vsLDSSSEditCovCor	Pointer to a correlation matrix
	C: float* for vsLSSSEditCovCor double* for vsLDSSSEditCovCor	
<i>cor_storage</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vsLSSSEditCovCor` routine replaces pointers to the array of means, covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cov_storage` and `cor_storage` parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the VSL Summary Statistics task descriptor.

Storage formats of a variance-covariance/correlation matrix

Parameter	Description
<code>VSL_SS_MATRIX_STORAGE_FULL</code>	A symmetric variance-covariance/correlation matrix is a one-dimensional array with elements $c(i, j)$ stored as $cp(i*p + j)$. The size of the array is $p*p$.
<code>VSL_SS_MATRIX_STORAGE_L_PACKED</code>	A symmetric variance-covariance/correlation matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + (2n - j)*(j - 1)/2)$ for $j \leq i$. The size of the array is $p*(p+1)/2$.
<code>VSL_SS_MATRIX_STORAGE_U_PACKED</code>	A symmetric variance-covariance/correlation matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + j*(j - 1)/2)$ for $i \leq j$. The size of the array is $p*(p+1)/2$.

vsLSSSEditPartialCovCor

Modifies the pointers to partial covariance/correlation parameters.

Syntax

Fortran:

```
status = vslssreditpartialcovcor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage)
```

```
status = vslssreditpartialcovcor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage)
```

C:

```
status = vslsSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

```
status = vsldSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>p_idx_array</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the array that encodes indices of subcomponents Z and Y of the random vector as described in section Mathematical Notation and Definitions . $p_{idx_array}[i]$ equals to -1 if the i -th component of the random vector belongs to Z 1, if the i -th component of the random vector belongs to Y .
<i>cov</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpartialcovcor REAL(KIND=8) DIMENSION(*) for vsldssreditpartialcovcor C: float* for vslsSSEditPartialCovCor double* for vsldSSEditPartialCovCor	Pointer to a covariance matrix
<i>cov_storage</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the covariance matrix
<i>cor</i>	Fortran: REAL(KIND=4) DIMENSION(*)	Pointer to a correlation matrix

Name	Type	Description
	<pre>for vslssreditpartialcovcor REAL(KIND=8) DIMENSION(*) for vslssreditpartialcovcor C: float*</pre>	
	<pre>for vsldSSEditPartialCovCor double* for vsldSSEditPartialCovCor</pre>	
cor_storage	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the correlation matrix
p_cov	Fortran: REAL(KIND=4) DIMENSION(*) <pre>for vslssreditpartialcovcor REAL(KIND=8) DIMENSION(*) for vslssreditpartialcovcor C: float*</pre>	Pointer to a partial covariance matrix
	<pre>for vsldSSEditPartialCovCor double* for vsldSSEditPartialCovCor</pre>	
p_cov_storage	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the partial covariance matrix
p_cor	Fortran: REAL(KIND=4) DIMENSION(*) <pre>for vslssreditpartialcovcor REAL(KIND=8) DIMENSION(*) for vslssreditpartialcovcor C: float*</pre>	Pointer to a partial correlation matrix
	<pre>for vsldSSEditPartialCovCor double* for vsldSSEditPartialCovCor</pre>	
p_cor_storage	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the partial correlation matrix

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditPartialCovCor` routine replaces pointers to covariance/correlation arrays, partial covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cov_storage`, `cor_storage`, `p_cov_storage`, and `p_cor_storage` parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the VSL Summary Statistics task descriptor.

`vslSSEditQuantiles`

Modifies the pointers to parameters related to quantile computations.

Syntax

Fortran:

```
status = vslssreditquantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage)

status = vsldssreditquantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage)
```

C:

```
status = vslsSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);

status = vsldSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<code>quant_order_n</code>	Fortran: INTEGER C: MKL_INT*	Pointer to the number of quantile orders
<code>quant_order</code>	Fortran: REAL(KIND=4) DIMENSION(*) for <code>vslssreditquantiles</code> REAL(KIND=8) DIMENSION(*) for <code>vsldssreditquantiles</code> C: float* for <code>vslsSSEditQuantiles</code> double* for <code>vsldSSEditQuantiles</code>	Pointer to the array of quantile orders

Name	Type	Description
<i>quants</i>	Fortran: REAL(KIND=4) DIMENSION(*) C: float*	Pointer to the array of quantiles for vslssreditquantiles REAL(KIND=8) DIMENSION(*) for vslsreditquantiles C: float*
<i>order_stats</i>	Fortran: REAL(KIND=4) DIMENSION(*) C: float*	Pointer to the array of order statistics for vslssreditquantiles REAL(KIND=8) DIMENSION(*) for vslsreditquantiles C: float*
<i>order_stats_storage</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the order statistics array

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the array that holds order statistics, and the storage format for the order statistics with values passed into the routine. See [Table "Storage format of matrix of observations and order statistics"](#) for possible values of the `order_statistics_storage` parameter. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged.

vsISSEditStreamQuantiles

Modifies the pointers to parameters related to quantile computations for streaming data.

Syntax

Fortran:

```
status = vslssreditstreamquantiles(task, quant_order_n, quant_order, quants, nparams,
params)
```

```
status = vslsSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params)
```

C:

```
status = vsldsseditstreamquantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

```
status = vsldSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>quant_order_n</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the number of quantile orders
<i>quant_order</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsSSEditStreamQuantiles REAL(KIND=8) DIMENSION(*) for vsldsseditstreamquantiles C: float* for vsldSSEditStreamQuantiles double* for vsldSSEditStreamQuantiles	Pointer to the array of quantile orders
<i>quants</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsSSEditStreamQuantiles REAL(KIND=8) DIMENSION(*) for vsldsseditstreamquantiles C: float* for vsldSSEditStreamQuantiles double* for vsldSSEditStreamQuantiles	Pointer to the array of quantiles
<i>nparams</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the number of the algorithm parameters
<i>params</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsSSEditStreamQuantiles	Pointer to the array of the algorithm parameters

Name	Type	Description
	<pre>REAL(KIND=8) DIMENSION(*) for vsldsseditstreamquantiles C: float* for vslsSSEditStreamQuantiles double* for vsldSSEditStreamQuantiles</pre>	

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditStreamQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the number of the algorithm parameters, and the array of the algorithm parameters with values passed into the routine. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged.

`vslSSEditPooledCovariance`

Modifies pooled/group covariance matrix array pointers.

Syntax

Fortran:

```
status = vslsseditpooledcovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov)
status = vsldsseditpooledcovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov)
```

C:

```
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov);
status = vsldSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK)	Descriptor of the task

Name	Type	Description
	C: VSLSSTaskPtr	
grp_indices	Fortran: INTEGER DIMENSION(*) C: MKL_INT*	Pointer to an array of size n . The i -th element of the array contains the number of the group the observation belongs to.
pld_mean	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for vslsreditpooledcovariance C: float* for vslsSEditPooledCovariance double* for vslsSEEditPooledCovariance	Pointer to the array of pooled means
pld_cov	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for vslsreditpooledcovariance C: float* for vslsSEEditPooledCovariance double* for vslsSEEditPooledCovariance	Pointer to the array that holds a pooled covariance matrix
grp_cov_indices	Fortran: INTEGER DIMENSION(*) C: MKL_INT*	Pointer to the array that contains indices of group covariance matrices to return
grp_means	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for vslsreditpooledcovariance C: float* for vslsSEEditPooledCovariance double* for vslsSEEditPooledCovariance	Pointer to the array of group means
grp_cov	Fortran: REAL(KIND=4) DIMENSION(*) for vslssreditpooledcovariance REAL(KIND=8) DIMENSION(*) for	Pointer to the array that holds group covariance matrices

Name	Type	Description
	vsldsseditpooledcovariance	
C:	float* for	
	vslsSSEditPooledCovariance	
	double* for	
	vsldSSEditPooledCovariance	

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vsISSEditPooledCovariance` routine replaces pointers to the array of group indices, the array of pooled means, the array for a pooled covariance matrix, and pointers to the array of indices of group matrices, the array of group means, and the array for group covariance matrices with values passed in the editors. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged. Use the `vsISSEditTask` routine to replace the storage format for pooled and group covariance matrices.

vsISSEditRobustCovariance

Modifies pointers to arrays related to a robust covariance matrix.

Syntax

Fortran:

```
status = vslsseditrobustcovariance(task, rcov_storage, nparams, params, rmean, rcov)
status = vsldsseditrobustcovariance(task, rcov_storage, nparams, params, rmean, rcov)
```

C:

```
status = vslsSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
status = vsldSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>rcov_storage</i>	Fortran: INTEGER	Pointer to the storage format of a robust covariance matrix

Name	Type	Description
<i>nparams</i>	C: MKL_INT*	
<i>params</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the number of method parameters
<i>rmean</i>	Fortran: REAL (KIND=4) DIMENSION (*) for vslsseditrobustcovariance REAL (KIND=8) DIMENSION (*) for vsldsseditrobustcovariance C: float* for vslsSSEditRobustCovariance double* for vsldSSEEditRobustCovariance	Pointer to the array of robust means
<i>rcov</i>	Fortran: REAL (KIND=4) DIMENSION (*) for vslsseditrobustcovariance REAL (KIND=8) DIMENSION (*) for vsldsseditrobustcovariance C: float* for vslsSSEditRobustCovariance double* for vsldSSEEditRobustCovariance	Pointer to a robust covariance matrix

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditRobustCovariance` routine uses values passed as parameters of the routine to replace:

- pointers to covariance matrix storage
- pointers to the number of method parameters and to the array of the method parameters of size `nparams`
- pointers to the arrays that hold robust means and covariance

See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `rcov_storage` parameter. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides a Translated Biweight S-estimator (TBS) for robust estimation of a variance-covariance matrix and mean [[Rocke96](#)]. Use one iteration of the Maronna algorithm with the reweighting step [[Maronna02](#)] to compute the initial point of the algorithm. Pack the parameters of the TBS algorithm into the `params` array and pass them into the editor. [Table "Structure of the Array of TBS Parameters"](#) describes the `params` structure.

Structure of the Array of TBS Parameters

Array Position	Algorithm Parameter	Description
0	ε	Breakdown point, the number of outliers the algorithm can hold. By default, the value is $(n-p) / (2n)$.
1	α	Asymptotic rejection probability, see details in [Rocke96]. By default, the value is 0.001.
2	δ	Stopping criterion: the algorithm is terminated if weights are changed less than δ . By default, the value is 0.001.
3	<code>max_iter</code>	Maximum number of iterations. The algorithm terminates after <code>max_iter</code> iterations. By default, the value is 10. If you set this parameter to zero, the function returns a robust estimate of the variance-covariance matrix computed using the Maronna method [Maronna02] only.

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.

`vslSSEditOutliersDetection`

Modifies array pointers related to multivariate outliers detection.

Syntax

Fortran:

```
status = vslsseditoutliersdetection(task, nparams, params, w)
status = vslsseditoutliersdetection(task, nparams, params, w)
```

C:

```
status = vslSSEditOutliersDetection(task, nparams, params, w);
status = vslDSSEditOutliersDetection(task, nparams, params, w);
```

Include Files

- Fortran 90: `mkl_vsl.f90`

- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
<i>nparams</i>	Fortran: INTEGER C: MKL_INT*	Pointer to the number of method parameters
<i>params</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditoutliersdetection REAL(KIND=8) DIMENSION(*) for vsldsseditoutliersdetection C: float* for vslsSSEditOutliersDetection double* for vsldSSEditOutliersDetection	Pointer to the array of method parameters
<i>w</i>	Fortran: REAL(KIND=4) DIMENSION(*) for vslsseditoutliersdetection REAL(KIND=8) DIMENSION(*) for vsldsseditoutliersdetection C: float* for vslsSSEditOutliersDetection double* for vsldSSEditOutliersDetection	Pointer to an array of size <i>n</i> . The array holds the weights of observations to be marked as outliers.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslsSSEditOutliersDetection` routine uses the parameters passed to replace

- the pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- the pointer to the array that holds the calculated weights of the observations

If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides the BACON algorithm ([Billor00]) for the detection of multivariate outliers. Pack the parameters of the BACON algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of BACON Parameters" describes the *params* structure.

Structure of the Array of BACON Parameters

Array Position	Algorithm Parameter	Description
0	Method to start the algorithm	The parameter takes one of the following possible values: VSL_SS_METHOD_BACON_MEDIAN_INIT, if the algorithm is started using the median estimate. This is the default value of the parameter. VSL_SS_METHOD_BACON_MAHALANOBIS_INIT, if the algorithm is started using the Mahalanobis distances.
1	α	One-tailed probability that defines the $(1 - \alpha)$ quantile of χ^2 distribution with p degrees of freedom. The recommended value is α / n , where n is the number of observations. By default, the value is 0.05.
2	δ	Stopping criterion; the algorithm is terminated if the size of the basic subset is changed less than δ . By default, the value is 0.005.

Output of the algorithm is the vector of weights, `BaconWeights`, such that `BaconWeights(i) = 0` if i -th observation is detected as an outlier. Otherwise `BaconWeights(i) = w(i)`, where `w` is the vector of input weights. If you do not provide the vector of input weights, `BaconWeights(i)` is set to 1 if the i -th observation is not detected as an outlier.

See additional details about usage model of the algorithm in the *Intel(R) MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.

vsISSEditMissingValues

Modifies pointers to arrays associated with the method of supporting missing values in a dataset.

Syntax

Fortran:

```
status = vslsseditmissingvalues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates)
```

```
status = vslseditmissingvalues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates)
```

C:

```
status = vsISSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

```
status = vsldSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task

The array holds m sets of simulated missing values for the matrix of observations.
estimates_n	Fortran: INTEGER C: MKL_INT*	Pointer to the number of estimates to be returned by the routine
estimates	Fortran: REAL(KIND=4) DIMENSION(*) for vslseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues C: float* for vslsSEditMissingValues double* for vsldSSEditMissingValues	Pointer to the array that holds estimates of the mean and a variance-covariance matrix.

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Current status of the task

Description

The vslsSEditMissingValues routine uses values passed as parameters of the routine to replace pointers to the number and the array of the method parameters, pointers to the number and the array of initial mean/variance-covariance estimates, the pointer to the number and the array of prior parameters, pointers

to the number and the array of simulated missing values, and pointers to the number and the array of the intermediate mean/covariance estimates. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Before you call the VSL Summary Statistics routines to process missing values, preprocess the dataset and denote missing observations with one of the following predefined constants:

- `VSL_SS_SNAN`, if the dataset is stored in single precision floating-point arithmetic
- `VSL_SS_DNAN`, if the dataset is stored in double precision floating-point arithmetic

Intel MKL provides the `VSI_SS_METHOD_MI` method to support missing values in the dataset based on the Multiple Imputation (MI) approach described in [Schafer97]. The following components support Multiple Imputation:

- Expectation Maximization (EM) algorithm to compute the start point for the Data Augmentation (DA) procedure
- DA function

NOTE The DA component of the MI procedure is simulation-based and uses the `VSL_BRNG_MCG59` basic random number generator with predefined `seed = 250` and the Gaussian distribution generator (`ICDF` method) available in Intel MKL [Gaussian].

Pack the parameters of the MI algorithm into the `params` array. Table "Structure of the Array of MI Parameters" describes the `params` structure.

Structure of the Array of MI Parameters

Array Position	Algorithm Parameter	Description
0	<code>em_iter_num</code>	Maximal number of iterations for the EM algorithm. By default, this value is 50.
1	<code>da_iter_num</code>	Maximal number of iterations for the DA algorithm. By default, this value is 30.
2	ϵ	Stopping criterion for the EM algorithm. The algorithm terminates if the maximal module of the element-wise difference between the previous and current parameter values is less than ϵ . By default, this value is 0.001.
3	<code>m</code>	Number of sets to impute
4	<code>missing_vals_num</code>	Total number of missing values in the datasets

You can also pass initial estimates into the EM algorithm by packing both the vector of means and the variance-covariance matrix as a one-dimensional array `init_estimates`. The size of the array should be at least $p + p(p + 1)/2$. For $i=0, \dots, p-1$, the `init_estimates[i]` array contains the initial estimate of means. The remaining positions of the array are occupied by the upper triangular part of the variance-covariance matrix.

If you provide no initial estimates for the EM algorithm, the editor uses the default values, that is, the vector of zero means and the unitary matrix as a variance-covariance matrix. You can also pass `prior` parameters for μ and Σ into the library: μ_0 , τ_m , and Λ^{-1} . Pack these parameters as a one-dimensional array `prior` with a size of at least

$$(p^2 + 3p + 4)/2.$$

The storage format is as follows:

- `prior[0], \dots, prior[p-1]` contain the elements of the vector μ_0 .

- $prior[p]$ contains the parameter τ .
- $prior[p+1]$ contains the parameter m .
- The remaining positions are occupied by the upper-triangular part of the inverted matrix Λ^{-1} .

If you provide no *prior* parameters, the editor uses their default values:

- The array of p zeros is used as μ_0 .
- τ is set to 0.
- m is set to p .
- The zero matrix is used as an initial approximate of Λ^{-1} .

The `EditMissingValues` editor returns m sets of imputed values and/or a sequence of parameter estimates drawn during the DA procedure.

The editor returns the imputed values as the `simul_missing_vals` array. The size of the array should be sufficient to hold m sets each of the `missing_vals_num` size, that is, at least $m * missing_vals_num$ in total. The editor packs the imputed values one by one in the order of their appearance in the matrix of observations.

For example, consider a task of dimension 4. The total number of observations n is 10. The second observation vector misses variables 1 and 2, and the seventh observation vector lacks variable 1. The number of sets to impute is $m=2$. Then, `simul_missing_vals[0]` and `simul_missing_vals[1]` contains the first and the second points for the second observation vector, and `simul_missing_vals[2]` holds the first point for the seventh observation. Positions 3, 4, and 5 are formed similarly.

To estimate convergence of the DA algorithm and choose a proper value of the number of DA iterations, request the sequence of parameter estimates that are produced during the DA procedure. The editor returns the sequence of parameters as a single array. The size of the array is

$$m * da_iter_num * (p + (p^2 + p) / 2)$$

where

- m is the number of sets of values to impute.
- `da_iter_num` is the number of DA iterations.
- The value $p + (p^2 + p) / 2$ determines the size of the memory to hold one set of the parameter estimates.

In each set of the parameters, the vector of means occupies the first p positions and the remaining $(p^2 + p) / 2$ positions are intended for the upper triangular part of the variance-covariance matrix.

Upon successful generation of m sets of imputed values, you can place them in cells of the data matrix with missing values and use the VSL Summary Statistics routines to analyze and get estimates for each of the m complete datasets.

NOTE Intel MKL implementation of the MI algorithm rewrites cells of the dataset that contain the `VSL_SS_SNAN`/`VSL_SS_DNAN` values. If you want to use the VSL Summary Statistics routines to process the data with missing values again, mask the positions of the empty cells.

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.

[vsISSEditCorParameterization](#)

Modifies pointers to arrays related to the algorithm of correlation matrix parameterization.

Syntax

Fortran:

```
status = vslssseditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
status = vslssteditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
```

C:

```
status = vslsSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
status = vslsSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr	Descriptor of the task
cor	Fortran: REAL(KIND=4) DIMENSION(*) for vslssseditcorparameterization REAL(KIND=8) DIMENSION(*) for vslssteditcorparameterization C: float* for vslsSSEditCorParameterization double* for vslsSSEditCorParameterization	Pointer to the correlation matrix
cor_storage	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the correlation matrix
pcor	Fortran: REAL(KIND=4) DIMENSION(*) for vslssseditcorparameterization REAL(KIND=8) DIMENSION(*) for vslssteditcorparameterization C: float* for vslsSSEditCorParameterization double* for vslsSSEditCorParameterization	Pointer to the parameterized correlation matrix
por_storage	Fortran: INTEGER C: MKL_INT*	Pointer to the storage format of the parameterized correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSEditCorParameterization` routine uses values passed as parameters of the routine to replace pointers to the correlation matrix, pointers to the correlation matrix storage format, a pointer to the parameterized correlation matrix, and a pointer to the parameterized correlation matrix storage format. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cor_storage` and `pcor_storage` parameters. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged.

Task Computation Routines

Task computation routines calculate statistical estimates on the data provided and parameters held in the task descriptor. After you create the task and initialize its parameters, you can call the computation routines as many times as necessary. [Table "VSL Summary Statistics Estimates Obtained with `vsISSCompute` Routine"](#) lists the statistical estimates that you can obtain using the `vsISSCompute` routine.

NOTE The VSL Summary Statistics computation routines do not signal floating-point errors, such as overflow or gradual underflow, or operations with NaNs (except for the missing values in the observations).

VSL Summary Statistics Estimates Obtained with `vsISSCompute` Routine

Estimate	Support of Observations Available in Blocks	Description
<code>VSL_SS_MEAN</code>	Yes	Computes the array of means.
<code>VSL_SS_2R_MOM</code>	Yes	Computes the array of the 2 nd order raw moments.
<code>VSL_SS_3R_MOM</code>	Yes	Computes the array of the 3 rd order raw moments.
<code>VSL_SS_4R_MOM</code>	Yes	Computes the array of the 4 th order raw moments.
<code>VSL_SS_2C_MOM</code>	Yes	Computes the array of the 2 nd order central moments.
<code>VSL_SS_3C_MOM</code>	Yes	Computes the array of the 3 rd order central moments.
<code>VSL_SS_4C_MOM</code>	Yes	Computes the array of the 4 th order central moments.
<code>VSL_SS_KURTOSIS</code>	Yes	Computes the array of kurtosis values.
<code>VSL_SS_SKEWNESS</code>	Yes	Computes the array of skewness values.
<code>VSL_SS_MIN</code>	Yes	Computes the array of minimum values.
<code>VSL_SS_MAX</code>	Yes	Computes the array of maximum values.

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_VARIATION	Yes	Computes the array of variation coefficients.
VSL_SS_COV	Yes	Computes a covariance matrix.
VSL_SS_COR	Yes	Computes a correlation matrix.
VSL_SS_POOLED_COV	No	Computes a pooled covariance matrix.
VSL_SS_GROUP_COV	No	Computes group covariance matrices.
VSL_SS_QUANTS	No	Computes quantiles.
VSL_SS_ORDER_STATS	No	Computes order statistics.
VSL_SS_ROBUST_COV	No	Computes a robust covariance matrix.
VSL_SS_OUTLIERS	No	Detects outliers in the dataset.
VSL_SS_PARTIAL_COV	No	Computes a partial covariance matrix.
VSL_SS_PARTIAL_COR	No	Computes a partial correlation matrix.
VSL_SS_MISSING_VALS	No	Supports missing values in datasets.
VSL_SS_PARAMTR_COR	No	Computes a parameterized correlation matrix.
VSL_SS_STREAM_QUANTS	Yes	Computes quantiles for streaming data.

[Table "VSL Summary Statistics Computation Methods"](#) lists estimate calculation methods supported by Intel MKL. See the *Intel(R) MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page for a detailed description of the methods.

VSL Summary Statistics Computation Method

Method	Description
VSL_SS_METHOD_FAST	Fast method for calculation of the estimates
VSL_SS_METHOD_1PASS	One-pass method for calculation of estimates
VSL_SS_METHOD_TBS	TBS method for robust estimation of covariance and mean
VSL_SS_METHOD_BACON	BACON method for detection of multivariate outliers
VSL_SS_METHOD_MI	Multiple imputation method for support of missing values
VSL_SS_METHOD_SD	Spectral decomposition method for parameterization of a correlation matrix
VSL_SS_METHOD_SQUANTS_ZW	Zhang-Wang (ZW) method for quantile estimation for streaming data
VSL_SS_METHOD_SQUANTS_ZW_FAST	Fast ZW method for quantile estimation for streaming data

You can calculate all requested estimates in one call of the routine. For example, to compute a kurtosis and covariance matrix using a fast method, pass a combination of the pre-defined parameters into the Compute routine as shown in the example below:

```
...
method = VSL_SS_METHOD_FAST;
task_params = VSL_SS_KURTOSIS|VSL_SS_COV;
...
status = vslSSCompute( task, task_params, method );
```

To compute statistical estimates for the next block of observations, you can do one of the following:

- copy the observations to memory, starting with the address available to the task
- use one of the appropriate [Editors](#) to modify the pointer to the new dataset in the task.

The library does not detect your changes of the dataset and computed statistical estimates. To obtain statistical estimates for a new matrix, change the observations and initialize relevant arrays. You can follow this procedure to compute statistical estimates for observations that come in portions. See [Table "VSL Summary Statistics Estimates Obtained with vsISSCompute Routine"](#) for information on such observations supported by the Intel MKL VSL Summary Statistics estimators.

To modify parameters of the task using the Task Editors, set the address of the targeted matrix of the observations or change the respective vector component indices. After you complete editing the task parameters, you can compute statistical estimates in the modified environment.

If the task completes successfully, the computation routine returns the zero status code. If an error is detected, the computation routine returns an error code. In particular, an error status code is returned in the following cases:

- the task pointer is `NULL`
- memory allocation has failed
- the calculation has failed for some other reason

NOTE You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vsISSCompute

Computes VSL Summary Statistics estimates.

Syntax

Fortran:

```
status = vslssscompute(task, estimates, method)
status = vslSSCompute(task, estimates, method)
```

C:

```
status = vslSSCompute(task, estimates, method);
status = vslDSSCompute(task, estimates, method);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: TYPE(VSL_SS_TASK)	Descriptor of the task

Name	Type	Description
	C: VSLSSTaskPtr	
<i>estimates</i>	Fortran: INTEGER (KIND=8) C: unsigned long long	List of statistical estimates to compute
<i>method</i>	Fortran: INTEGER C: MKL_INT	Method to be used in calculations

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Current status of the task

Description

The `vslSSCompute` routine calculates statistical estimates passed as the *estimates* parameter using the algorithms passed as the *method* parameter of the routine. The computations are done in the context of the task descriptor that contains pointers to all required and optional, if necessary, properly initialized arrays. In one call of the function, you can compute several estimates using proper methods for their calculation. See [Table "VSL Summary Statistics Estimates Obtained with Compute Routine"](#) for the list of the estimates that you can calculate with the `vslSSCompute` routine. See [Table "VSL Summary Statistics Computation Methods"](#) for the list of possible values of the *method* parameter.

To initialize single or double precision version task parameters, use the single (`vslssscompute`) or double (`vsldsscompute`) version of the editor, respectively. To initialize parameters of the integer type, use an integer version of the editor (`vslisscompute`).

NOTE Requesting a combination of the `VSL_SS_MISSING_VALS` value and any other estimate parameter in the `Compute` function results in processing only the missing values.

Task Destructor

Task destructor is the `vslSSDeleteTask` routine intended to delete task objects and release memory.

`vslSSDeleteTask`

Destroys the task object and releases the memory.

Syntax

Fortran:

```
status = vslssdeletetask(task)
```

C:

```
status = vslSSDeleteTask(&task);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE(VSL_SS_TASK) C: VSLSSTaskPtr*	Descriptor of the task to destroy

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Sets to VSL_STATUS_OK if the task is deleted; otherwise a non-zero code is returned.

Description

The `vslSSDeleteTask` routine deletes the task descriptor object, releases the memory allocated for the structure, and sets the task pointer to `NULL`. If `vslSSDeleteTask` fails to delete the task successfully, it returns an error code.

NOTE Call of the destructor with the `NULL` pointer as the parameter results in termination of the function with no system crash.

Usage Examples

The following examples show various standard operations with Summary Statistics routines.

Calculating Fixed Estimates for Fixed Data

The example shows recurrent calculation of the same estimates with a given set of variables for the complete life cycle of the task in the case of a variance-covariance matrix. The set of vector components to process remains unchanged, and the data comes in blocks. Before you call the `vslSSCompute` routine, initialize pointers to arrays for mean and covariance and set buffers.

```
...
double w[2];
double indices[DIM] = {1, 0, 1};

/* calculating mean for 1st and 3d random vector components */
/* Initialize parameters of the task */
p = DIM;
n = N;

xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

status = vslSSNewTask( &task, &p, &n, &xstorage, x, 0, indices );

status = vslSSEditTask ( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vslSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );
```

You can process data arrays that come in blocks as follows:

```
for ( i = 0; i < num_of_blocks; i++ )
{
    status = vslSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );
    /* Read new data block into array x */
}
...
```

Calculating Different Estimates for Variable Data

The context of your calculation may change in the process of data analysis. The example below shows the data that comes in two blocks. You need to estimate a covariance matrix for the complete data, and the third central moment for the second block of the data using the weights that were accumulated for the previous datasets. The second block of the data is stored in another array. You can proceed as follows:

```
/* Set parameters for the task */
p = DIM;
n = N;
xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

/* Create task */
status = vslSSNewTask( &task, &p, &n, &xstorage, x1, 0, indices );

/* Initialize the task parameters */
status = vslSSEditTask( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vslSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );

/* Calculate covariance for the x1 data */
status = vslSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );

/* Initialize array of the 3d central moments and pass the pointer to the task */
for ( i = 0; i < p; i++ ) c3_m[i] = 0.0;

/* Modify task context */
status = vslSSEditTask( task, VSL_SS_ED_3C_MOM, c3_m );
status = vslSSEditTask( task, VSL_SS_ED_OBSERV, x2 );

/* Calculate covariance for the x1 & x2 data block */
/* Calculate the 3d central moment for the 2nd data block using earlier accumulated weight */
status = vslSSCompute( task, VSL_SS_COV|VSL_SS_3C_MOM, VSL_SS_METHOD_FAST );
...
status = vslSSDeleteTask( &task );
```

Similarly, you can modify indices of the variables to be processed for the next data block.

Mathematical Notation and Definitions

The following notations are used in the mathematical definitions and the description of the Intel MKL VSL Summary Statistics functions.

Matrix and Weights of Observations

For a random p -dimensional vector $\xi = (\xi_1, \dots, \xi_i, \dots, \xi_p)$, this manual denotes the following:

- $(X)_{i=(x_{ij})_{j=1\dots n}}$ is the result of n independent observations for the i -th component ξ_i of the vector ξ .
- The two-dimensional array $X=(x_{ij})_{p \times n}$ is the matrix of observations.
- The column $[X]_{j=(x_{ij})_{i=1\dots p}}$ of the matrix X is the j -th observation of the random vector ξ .

Each observation $[X]_j$ is assigned a non-negative weight w_j , where

- The vector $(w_j)_{j=1\dots n}$ is a vector of weights corresponding to n observations of the random vector ξ .
-

$$W = \sum_{i=1}^n w_i$$

is the accumulated weight corresponding to observations x .

Vector of sample means

$$M(X) = (M_1(X), \dots, M_p(X)) \text{ with } M_i(X) = \frac{1}{w} \sum_{j=1}^n w_j x_{ij}$$

for all $i = 1, \dots, p$.

Vector of sample variances

$$V(X) = (V_1(X), \dots, V_p(X)) \text{ with } V_i(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^2, B = W - \sum_{j=1}^n w_j^2 / W$$

for all $i = 1, \dots, p$.

Vector of sample raw/algebraic moments of k-th order, $k \geq 1$

$$R^{(k)}(X) = (R_1^{(k)}(X), \dots, R_p^{(k)}(X)) \text{ with } R_i^{(k)}(X) = \frac{1}{W} \sum_{j=1}^n w_j x_{ij}^k$$

for all $i = 1, \dots, p$.

Vector of sample central moments of the third and the fourth order

$$C^{(k)}(X) = (C_1^{(k)}(X), \dots, C_p^{(k)}(X)) \text{ with } C_i^{(k)}(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^k, B = \sum_{j=1}^n w_j$$

for all $i = 1, \dots, p$ and $k = 3, 4$.

Vector of sample excess kurtosis values

$$B(X) = (B_1(X), \dots, B_p(X)) \text{ with } B_i(X) = \frac{C_i^{(4)}(X)}{V_i^2(X)} - 3$$

for all $i = 1, \dots, p$.

Vector of sample skewness values

$$\Gamma(X) = (\Gamma_1(X), \dots, \Gamma_p(X)) \text{ with } \Gamma_i(X) = \frac{C_i^{(3)}(X)}{V_i^{1.5}(X)}$$

for all $i = 1, \dots, p$.

Vector of sample variation coefficients

$$VC(X) = (VC_1(X), \dots, VC_p(X)) \text{ with } VC_i(X) = \frac{V_i^{0.5}(X)}{M_i(X)}$$

for all $i = 1, \dots, p$.

Matrix of order statistics

Matrix $Y = (y_{ij})_{pxn}$, in which the i -th row $(Y)_i = (y_{ij})_{j=1 \dots n}$ is obtained as a result of sorting in the ascending order of row $(X)_i = (x_{ij})_{j=1 \dots n}$ in the original matrix of observations.

Vector of sample minimum values

$$Min(X) = (Min_1(X), \dots, Min_p(X)), \text{ where } Min_i(X) = y_{i1}$$

for all $i = 1, \dots, p$.

Vector of sample maximum values

$$Max(X) = (Max_1(X), \dots, Max_p(X)), \text{ where } Max_i(X) = y_{in}$$

for all $i = 1, \dots, p$.

Vector of sample median values

$$Med(X) = (Med_1(X), \dots, Med_p(X)), \text{ where } Med_i(X) = \begin{cases} y_{i,(n+1)/2}, & \text{if } n \text{ is odd} \\ (y_{i,n/2} + y_{i,n/2+1})/2, & \text{if } n \text{ is even} \end{cases}$$

for all $i = 1, \dots, p$.

Vector of sample quantile values

For a positive integer number q and k belonging to the interval $[0, q-1]$, point z_i is the k -th q quantile of the random variable ξ_i if $P\{\xi_i \leq z_i\} \geq \beta$ and $P\{\xi_i \leq z_i\} \geq 1 - \beta$, where

- P is the probability measure.
- $\beta = k/n$ is the quantile order.

The calculation of quantiles is as follows:

$j = [(n-1)\beta]$ and $f = \{(n-1)\beta\}$ as integer and fractional parts of the number $(n-1)\beta$, respectively, and the vector of sample quantile values is

$$\mathcal{Q}(X, \beta) = (\mathcal{Q}_1(X, \beta), \dots, \mathcal{Q}_p(X, \beta))$$

where

$$(\mathcal{Q}_i(X, \beta)) = y_{i, j+1} + f(y_{i, j+2} - y_{i, j+1})$$

for all $i = 1, \dots, p$.

Variance-covariance matrix

$$C(X) = (c_{ij}(X))_{p \times p}$$

where

$$c_{ij}(X) = \frac{1}{B} \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X)), B = W - \sum_{j=1}^n w_j^2 / W$$

Pooled and group variance-covariance matrices

The set $N = \{1, \dots, n\}$ is partitioned into non-intersecting subsets

$$G_i, i = 1..g, N = \bigcup_{i=1}^g G_i$$

The observation $[X]_j = (x_{ij})_{i=1..p}$ belongs to the group r if $j \in G_r$. One observation belongs to one group only. The group mean and variance-covariance matrices are calculated similarly to the formulas above:

$$M^{(r)}(X) = (M_1^{(r)}(X), \dots, M_p^{(r)}(X)) \text{ with } M_i^{(r)}(X) = \frac{1}{W^{(r)}} \sum_{j \in G_r} w_j x_{ij}, W^{(r)} = \sum_{j \in G_r} w_j$$

for all $i = 1, \dots, p$,

$$C^{(r)}(X) = (c_{ij}^{(r)}(X))_{p \times p}$$

where

$$c_{ij}^{(r)}(X) = \frac{1}{B^{(r)}} \sum_{k \in G_r} w_k (x_{ik} - M_i^{(r)}(X))(x_{jk} - M_j^{(r)}(X)), B^{(r)} = W^{(r)} - \sum_{j \in G_r} w_j^2 / W^{(r)}$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

A pooled variance-covariance matrix and a pooled mean are computed as weighted mean over group covariance matrices and group means, correspondingly:

$$M^{pooled}(X) = (M_1^{pooled}(X), \dots, M_p^{pooled}(X)) \text{ with } M_i^{pooled}(X) = \frac{1}{W^{(1)} + \dots + W^{(g)}} \sum_{r=1}^g W^{(r)} M_i^{(r)}(X)$$

for all $i = 1, \dots, p$,

$$C^{pooled}(X) = (c_{ij}^{pooled}(X))_{p \times p}, c_{ij}^{pooled}(X) = \frac{1}{B^{(1)} + \dots + B^{(g)}} \sum_{r=1}^g B^{(r)} c_{ij}^{(r)}(X)$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

Correlation matrix

$$R(X) = (r_{ij}(X))_{p \times p}, \text{ where } r_{ij}(X) = \frac{c_{ij}}{\sqrt{c_{ii}c_{jj}}}$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

Partial variance-covariance matrix

For a random vector ξ partitioned into two components Z and Y , a variance-covariance matrix C describes the structure of dependencies in the vector ξ :

$$C(X) = \begin{bmatrix} C_Z(X) & C_{ZY}(X) \\ C_{YZ}(X) & C_Y(X) \end{bmatrix}.$$

The partial covariance matrix $P(X) = (p_{ij}(X))_{k \times k}$ is defined as

$$P(X) = C_Y(X) - C_{YZ}(X)C_Z^{-1}(X)C_{ZY}(X).$$

where k is the dimension of Y .

Partial correlation matrix

The following is a partial correlation matrix for all $i = 1, \dots, k$ and $j = 1, \dots, k$:

$$RP(X) = (rp_{ij}(X))_{k \times k}, \text{ where } rp_{ij}(X) = \frac{p_{ij}(X)}{\sqrt{p_{ii}(X)p_{jj}(X)}}$$

where

- k is the dimension of Y .
- $p_{ij}(X)$ are elements of the partial variance-covariance matrix.

Fourier Transform Functions

The general form of the discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_1 = 0, \dots, n_1-1$ ($l = 1, \dots, d$), where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the inverse (backward) transform. In the forward transform, the input (periodic) sequence $\{w_{j_1, j_2, \dots, j_d}\}$ belongs to the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform are represented by complex-valued sequences and complex-valued conjugate-even sequences.

The Intel® Math Kernel Library (Intel® MKL) provides an interface for computing a discrete Fourier transform through the fast Fourier transform algorithm. This chapter describes the following implementations of the fast Fourier transform functions available in Intel MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#))
- Cluster FFT functions for distributed-memory architectures (available with Intel® MKL for the Linux* and Windows* operating systems only)

NOTE Intel MKL also supports the FFTW3* interfaces to the fast Fourier transform functionality for shared-memory (SMP) systems.

Both FFT and Cluster FFT functions compute an FFT in five steps:

1. Allocate a fresh descriptor for the problem with a call to the [DftiCreateDescriptor](#) or [DftiCreateDescriptorDM](#) function. The descriptor captures the configuration of the transform, such as the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), and scaling factors. Many of the configuration settings are assigned default values in this call which you might need to modify in your application.
2. Optionally adjust the descriptor configuration with a call to the [DftiSetValue](#) or [DftiSetValueDM](#) function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the [DftiGetValue](#) or [DftiGetValueDM](#) function.
3. Commit the descriptor with a call to the [DftiCommitDescriptor](#) or [DftiCommitDescriptorDM](#) function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the [DftiComputeForward](#)/[DftiComputeBackward](#) or [DftiComputeForwardDM](#)/[DftiComputeBackwardDM](#) functions as many times as needed. Because the descriptor is defined and committed separately, all that the compute functions do is take the input and output data and compute the transform as defined. To modify any configuration parameters for another call to a compute function, use [DftiSetValue](#) followed by [DftiCommitDescriptor](#) ([DftiSetValueDM](#) followed by [DftiCommitDescriptorDM](#)) or create and commit another descriptor.
5. Deallocate the descriptor with a call to the [DftiFreeDescriptor](#) or [DftiFreeDescriptorDM](#) function. This returns the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the [DftiErrorClass](#) or [DftiErrorMessage](#) function.

The FFT functions support lengths with arbitrary factors. You can improve performance of the Intel MKL FFT if the length of your data vector permits factorization into powers of optimized radices. See the *Intel MKL User's Guide* for specific radices supported efficiently.

NOTE The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide efficient tools for conversion to and from polar representation (see [Example "Conversion from Cartesian to polar representation of complex data"](#) and [Example "Conversion from polar to Cartesian representation of complex data"](#)).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional transforms (of up to seven dimensions) and offers both Fortran and C interfaces for all transform functions.

[Table "FFT Functions in Intel MKL"](#) lists FFT functions implemented in Intel MKL:

FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptor	Allocates the descriptor data structure and initializes it with default configuration values.
DftiCommitDescriptor	Performs all initialization for the actual FFT computation.
DftiFreeDescriptor	Frees memory allocated for a descriptor.
DftiCopyDescriptor	Makes a copy of an existing descriptor.
FFT Computation Functions	
DftiComputeForward	Computes the forward FFT.
DftiComputeBackward	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValue	Sets one particular configuration parameter with the specified configuration value.
DftiGetValue	Gets the value of one particular configuration parameter.
Status Checking Functions	
DftiErrorClass	Checks if the status reflects an error of a predefined class.

Function Name	Operation
DftiErrorMessage	Translates the numeric value of an error status into a message.

Computing an FFT

You can find code examples that compute transforms in the [Fourier Transform Functions Code Examples](#) section in the Appendix C.

Usually you can compute an FFT by five function calls (refer to the [usage model](#) for details). A single data structure, the descriptor, stores configuration parameters that can be changed independently.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of several configuration parameters. Default settings for some of these parameters are as follows:

- Scale factor: none
- Number of data sets: one
- Data storage: contiguous
- Placement of results: in-place (the computed result overwrites the input data)

The default settings can be changed one at a time through the function `DftiSetValue` as illustrated in the [Example "Changing Default Settings \(Fortran\)"](#) and [Example "Changing Default Settings \(C\)"](#).

FFT Interface

The Intel MKL FFT functions are provided with the Fortran and C interfaces. Fortran 95 is required because it offers features that have no counterpart in FORTRAN 77.

NOTE The Fortran interface of the FFT computation functions requires one-dimensional data arrays for any dimension of FFT problem. For multidimensional transforms, pass the address of the first column of the multidimensional data to the computation functions.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

To use the FFT functions, you need to access the module `MKL_DFTI` through the Fortran `use` statement or include `mkl_dfti.h` in C.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR`, named constants representing various names of configuration parameters and their possible values, and overloaded functions through the generic functionality of Fortran 95.

The C interface provides the `DFTI_DESCRIPTOR_HANDLE` type, named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`, and functions, some of which accept different numbers of input arguments.

NOTE The current version of the library may not support some of the FFT functions or functionality described in the subsequent sections of this chapter. You can find the complete list of the implementation-specific exceptions in the Intel MKL Release Notes.

For the main categories of Intel MKL FFT functions, see [FFT Functions](#).

Descriptor Manipulation Functions

This category contains the following functions: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

DftiCreateDescriptor

Allocates the descriptor data structure and initializes it with default configuration values.

Syntax

Fortran:

```
status = DftiCreateDescriptor( desc_handle, precision, forward_domain, dimension,
length )
```

C:

```
status = DftiCreateDescriptor(&desc_handle, precision, forward_domain, dimension,
length);
```

Include Files

- FORTRAN 90: mkl_dfti.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>precision</i>	FORTRAN: INTEGER C: enum	Precision of the transform: DFTI_SINGLE or DFTI_DOUBLE.
<i>forward_domain</i>	FORTRAN: INTEGER C: enum	Forward domain of the transform: DFTI_COMPLEX or DFTI_REAL.
<i>dimension</i>	FORTRAN: INTEGER C: MKL_LONG	Dimension of the transform.
<i>length</i>	FORTRAN: INTEGER if <i>dimension</i> = 1. Array INTEGER, DIMENSION (*) otherwise. C: MKL_LONG if <i>dimension</i> = 1. Array of type MKL_LONG otherwise.	Length of the transform for a one-dimensional transform. Lengths of each dimension for a multi-dimensional transform.

Output Parameters

Name	Type	Description
<i>desc_handle</i>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings for the precision, forward domain, dimension, and length of the desired transform. Because memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function that can be found in software packages or libraries that implement more traditional algorithms for computing an FFT. This function does not perform any significant computational work such as computation of twiddle factors. The function `DftiCommitDescriptor` does this work after the function `DftiSetValue` has set values of all necessary parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```

! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.

INTERFACE DftiCreateDescriptor

  FUNCTION some_actual_function_1d(desc, precision, domain, dim, length)
    INTEGER :: some_actual_function_1d
    ...
    INTEGER, INTENT(IN) :: length
  END FUNCTION some_actual_function_1d

  FUNCTION some_actual_function_md(desc, precision, domain, dim, lengths)
    INTEGER :: some_actual_function_md
    ...
    INTEGER, INTENT(IN), DIMENSION(*) :: lengths
  END FUNCTION some_actual_function_md

  ...

END INTERFACE DftiCreateDescriptor

```

Note that the function is overloaded: the actual parameter for the formal parameter `length` can be a scalar or a rank-one array.

The function is also overloaded with respect to the type of the `precision` parameter in order to provide an option of using a precision-specific function for the generic name. Using more specific functions can reduce the size of statically linked executable for the applications using only single-precision FFTs or only double-precision FFTs. To use specific functions, change the "USE MKL_DFTI" statement in your program unit to one of the following:

```

USE MKL_DFTI, FORGET=>DFTI_SINGLE, DFTI_SINGLE=>DFTI_SINGLE_R
USE MKL_DFTI, FORGET=>DFTI_DOUBLE, DFTI_DOUBLE=>DFTI_DOUBLE_R

```

where the name "FORGET" can be replaced with any name that is not used in the program unit.

```

/* C prototype.
 * Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
 */
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
                           enum DFTI_CONFIG_VALUE precision,
                           enum DFTI_CONFIG_VALUE domain,

```

```

    MKL_LONG dimension, ... /* length/lengths */ );

#define DftiCreateDescriptor(desc,prec,domain,dim,sizes) \
    ((prec)==DFTI_SINGLE && (dim)==1) ? \
        some_actual_function_s1d((desc),(domain),(MKL_LONG)(sizes)) : \
    ...

```

Variable *length/lengths* is interpreted as a scalar (`MKL_LONG`) or an array (`MKL_LONG*`), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, an optimizing compiler retains only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel MKL FFT header file, as follows:

```
#include "mkl_dfti.h"
#undef DftiCreateDescriptor
```

DftiCommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
status = DftiCommitDescriptor( desc_handle )
```

C:

```
status = DftiCommitDescriptor(desc_handle);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: <code>DFTI_DESCRIPTOR</code> C: <code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.

Output Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: <code>DFTI_DESCRIPTOR</code> C: <code>DFTI_DESCRIPTOR_HANDLE</code>	Updated FFT descriptor.
<code>status</code>	FORTRAN: <code>INTEGER</code> C: <code>MKL_LONG</code>	Function completion status.

Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, committing the descriptor performs all initialization that is required for the actual FFT computation. The initialization done by the function may involve exploring different factorizations of the input length to find the optimal computation method.

If you call the `DftiSetValue` function to change configuration parameters of a committed descriptor see [Descriptor Configuration Functions](#)), you must re-commit the descriptor before invoking a computation function. Typically, a committal function call is immediately followed by a computation function call (see [FFT Computation Functions](#)).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCommitDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
FUNCTION some_actual_function_1 ( Desc_Handle )
INTEGER :: some_actual_function_1
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
END FUNCTION some_actual_function_1
END INTERFACE DftiCommitDescriptor
```

```
/* C prototype */
MKL_LONG DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );
```

DftiFreeDescriptor

Frees the memory allocated for a descriptor.

Syntax

Fortran:

```
status = DftiFreeDescriptor( desc_handle )
```

C:

```
status = DftiFreeDescriptor(&desc_handle);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: DESCRIPTOR_HANDLE C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.

Output Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: DESCRIPTOR_HANDLE C: DFTI_DESCRIPTOR_HANDLE	Memory for the FFT descriptor is released.
<code>status</code>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function frees all memory allocated for a descriptor.

 **NOTE** Memory allocation/deallocation inside Intel MKL is managed by Intel MKL memory management software. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the memory management software sometimes does not return the memory space to the OS, but considers the space free and can reuse it for future memory allocation. See [Example "mkl_free_buffers Usage with FFT Functions"](#) in the description of the service function `FreeBuffers` on how to use Intel MKL memory management software and release memory to the OS.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiFreeDescriptor
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_3( Desc_Handle )
INTEGER :: some_actual_function_3
TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
END FUNCTION some_actual_function_3
END INTERFACE DftiFreeDescriptor
```

```
/* C prototype */
MKL_LONG DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

DftiCopyDescriptor

Makes a copy of an existing descriptor.

Syntax

Fortran:

```
status = DftiCopyDescriptor( desc_handle_original, desc_handle_copy )
```

C:

```
status = DftiCopyDescriptor(desc_handle_original, &desc_handle_copy);
```

Include Files

- FORTRAN 90: mkl_dfti.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>desc_handle_original</i>	FORTRAN: DESCRIPTOR_HANDLE C: DFTI_DESCRIPTOR_HANDLE	The FFT descriptor to copy.

Output Parameters

Name	Type	Description
<i>desc_handle_copy</i>	FORTRAN: DESCRIPTOR_HANDLE C: DFTI_DESCRIPTOR_HANDLE	The copy of the FFT descriptor.
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function makes a copy of an existing descriptor and provides a pointer to it. The purpose is that all information of the original descriptor will be maintained even if the original is destroyed via the free descriptor function `DftiFreeDescriptor`.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```

! Fortran interface
INTERFACE DftiCopyDescriptor
! Note that the body provided here is to illustrate the different
! argument list and types of dummy arguments. The interface
! does not guarantee what the actual function names are.
! Users can only rely on the function name following the
! keyword INTERFACE
FUNCTION some_actual_function_2( Desc_Handle_Original,
Desc_Handle_Copy )
INTEGER :: some_actual_function_2
TYPE(DFTI_DESCRIPTOR),^POINTER :: Desc_Handle_Original, Desc_Handle_Copy
END FUNCTION some_actual_function_2
END INTERFACE DftiCopyDescriptor

```

```

/* C prototype */
MKL_LONG DftiCopyDescriptor( DFTI_DESCRIPTOR_HANLDE, DFTI_DESCRIPTOR_HANDLE * );

```

FFT Computation Functions

This category contains the following functions: compute the forward transform and compute the backward transform.

DftiComputeForward

Computes the forward FFT.

Syntax

Fortran:

```
status = DftiComputeForward( desc_handle, x_inout )
status = DftiComputeForward( desc_handle, x_in, y_out )
status = DftiComputeForward( desc_handle, xre_inout, xim_inout )
status = DftiComputeForward( desc_handle, xre_in, xim_in, yre_out, yim_out )
```

C:

```
status = DftiComputeForward(desc_handle, x_inout);
status = DftiComputeForward(desc_handle, x_in, y_out);
status = DftiComputeForward(desc_handle, xre_inout, xim_inout);
status = DftiComputeForward(desc_handle, xre_in, xim_in, yre_out, yim_out);
```

Input Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<code>x_inout</code> , <code>x_in</code>	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform, specified in the DFTI_PRECISION configuration setting.	Data to be transformed in case of a real forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.
<code>xre_inout</code> , <code>xim_inout</code> , <code>xre_in</code> , <code>xim_in</code>	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_in` to `DFTI_NOT_INPLACE`

Output Parameters

Name	Type	Description
<code>y_out</code>	FORTRAN: Array <code>REAL(KIND=WP)</code> or <code>COMPLEX(KIND=WP)</code> , <code>DIMENSION(*)</code> , where type and working precision <code>WP</code> must be consistent with the forward domain and precision specified in the descriptor. C: Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	The transformed data in case of a real backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
<code>xre_inout,</code> <code>xim_inout,</code> <code>yre_out, yim_out</code>	FORTRAN: Array <code>REAL(KIND=WP)</code> or <code>COMPLEX(KIND=WP)</code> , <code>DIMENSION(*)</code> , where type and working precision <code>WP</code> must be consistent with the forward domain and precision specified in the descriptor. C: Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the transformed data in the case of a complex backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
<code>status</code>	FORTRAN: <code>INTEGER</code> C: <code>MKL_LONG</code>	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_out` to `DFTI_NOT_INPLACE`

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl.h`

Description

The `DftiComputeForward` function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, this function computes the forward FFT, that is, the `transform` with the minus sign in the exponent, $\delta = -1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the function is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `FTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
```

```

! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeForward

FUNCTION some_actual_function_1(desc,sSrcDst)
  INTEGER some_actual_function_1
  REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
  ...
END FUNCTION some_actual_function_1

FUNCTION some_actual_function_2(desc,cSrcDst)
  INTEGER some_actual_function_2
  COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
  ...
END FUNCTION some_actual_function_2

FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
  INTEGER some_actual_function_3
  REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
  REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
  ...
END FUNCTION some_actual_function_3
...
END INTERFACE DftiComputeForward

```

The Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular stride pattern capable of describing multidimensional array layout (see also [3] and the more detailed discussion in [DFTI_INPUT_STRIDES](#), [DFTI_OUTPUT_STRIDES](#)), and the function requires that the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

```

DftiComputeBackward

Computes the backward FFT.

Syntax

Fortran:

```

status = DftiComputeBackward( desc_handle, x_inout )
status = DftiComputeBackward( desc_handle, y_in, x_out )
status = DftiComputeBackward( desc_handle, xre_inout, xim_inout )
status = DftiComputeBackward( desc_handle, yre_in, yim_in, xre_out, xim_out )

```

C:

```

status = DftiComputeBackward(desc_handle, x_inout);

```

```

status = DftiComputeBackward(desc_handle, y_in, x_out);
status = DftiComputeBackward(desc_handle, xre_inout, xim_inout);
status = DftiComputeBackward(desc_handle, yre_in, yim_in, xre_out, xim_out);

```

Input Parameters

Name	Type	Description
<code>desc_handle</code>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<code>x_inout, y_in</code>	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform, specified in the DFTI_PRECISION configuration setting.	Data to be transformed in case of a real backward domain, determined by the DFTI_FORWARD_DOMAIN configuration setting.
<code>xre_inout,</code> <code>xim_inout,</code> <code>yre_in, yim_in</code>	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex backward domain, determined by the DFTI_FORWARD_DOMAIN configuration setting.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_in` to `DFTI_NOT_INPLACE`

Output Parameters

Name	Type	Description
<code>x_out</code>	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. C: Array of type float or double depending on the precision of the transform.	The transformed data in case of a real forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.
<code>xre_inout,</code> <code>xim_inout,</code> <code>xre_out, xim_out</code>	FORTRAN: Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor.	Real and imaginary parts of the transformed data in the case of a complex forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.

Name	Type	Description
	C: Array of type float or double depending on the precision of the transform.	
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_out` to `DFTI_NOT_INPLACE`

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl.h`

Description

The function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, the `DftiComputeBackward` function computes the inverse FFT, that is, the `transform` with the plus sign in the exponent, $\delta = +1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the computation function is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Interface and Prototype

```

! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeBackward

  FUNCTION some_actual_function_1(desc,sSrcDst)
    INTEGER some_actual_function_1
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
    ...
  END FUNCTION some_actual_function_1

  FUNCTION some_actual_function_2(desc,cSrcDst)
    INTEGER some_actual_function_2
    COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
    ...
  END FUNCTION some_actual_function_2

  FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
    INTEGER some_actual_function_3
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
    ...
  
```

```

END FUNCTION some_actual_function_3
...
END INTERFACE DftiComputeBackward

```

The Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular stride pattern capable of describing multidimensional array layout (see also [3] and the more detailed discussion in [DFTI_INPUT_STRIDES](#), [DFTI_OUTPUT_STRIDES](#)), and the function requires that the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

```

/* C prototype */
MKL_LONG DftiComputeBackward( DFTI_DESCRIPTOR_HANDLE, void *, ... );

```

Descriptor Configuration Functions

This category contains the following functions: the value setting function [DftiSetValue](#) sets one particular configuration parameter to an appropriate value, and the value getting function [DftiGetValue](#) reads the value of one particular configuration parameter. While all configuration parameters are readable, you cannot set a few of them. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, which is derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

DftiSetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
status = DftiSetValue( desc_handle, config_param, config_val )
```

C:

```
status = DftiSetValue(desc_handle, config_param, config_val);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>desc_handle</i>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<i>config_param</i>	FORTRAN: INTEGER C: enum	Configuration parameter.
<i>config_val</i>	Depends on the configuration parameter.	Configuration value.

Output Parameters

Name	Type	Description
<i>desc_handle</i>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	Updated FFT descriptor.
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- DFTI_PRECISION
- DFTI_FORWARD_DOMAIN
- DFTI_DIMENSION, DFTI_LENGTH
- DFTI_PLACEMENT
- DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE
- DFTI_NUMBER_OF_USER_THREADS
- DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES
- DFTI_NUMBER_OF_TRANSFORMS
- DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE
- DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE
- DFTI_PACKED_FORMAT
- DFTI_WORKSPACE
- DFTI_ORDERING

The `DftiSetValue` function cannot be used to change configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS`. Use the `DftiCreateDescriptor` function to set them.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

DftiGetValue

Gets the configuration value of one particular configuration parameter.

Syntax

Fortran:

```
status = DftiGetValue( desc_handle, config_param, config_val )
```

C:

```
status = DftiGetValue(desc_handle, config_param, &config_val);
```

Include Files

- FORTRAN 90: mkl_dfti.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>desc_handle</i>	FORTRAN: DFTI_DESCRIPTOR C: DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<i>config_param</i>	FORTRAN: INTEGER C: enum	Configuration parameter. See Table "Configuration Parameters" for allowable values of <i>config_param</i> .

Output Parameters

Name	Type	Description
<i>config_val</i>	Depends on the configuration parameter.	Configuration value.
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Function completion status.

Description

This function gets the configuration value of one particular configuration parameter. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- DFTI_PRECISION

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. The functions in this category check that status. The first function is a logical function that checks whether the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

DftiErrorClass

Checks whether the status reflects an error of a predefined class.

Syntax

Fortran:

```
predicate = DftiErrorClass( status, error_class )
```

C:

```
predicate = DftiErrorClass(status, error_class);
```

Include Files

- FORTRAN 90: mkl_dfti.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<i>status</i>	FORTRAN: INTEGER C: MKL_LONG	Completion status of an FFT function.
<i>error_class</i>	FORTRAN: INTEGER C: MKL_LONG	Predefined error class.

Output Parameters

Name	Type	Description
<i>predicate</i>	FORTRAN: LOGICAL C: MKL_LONG	Result of checking.

Description

The FFT interface in Intel MKL provides a set of predefined error classes listed in [Table "Predefined Error Classes"](#). They are named constants and have the type `INTEGER` in Fortran and `MKL_LONG` in C.

Predefined Error Classes

Named Constants	Comments
DFTI_NO_ERROR	No error. The zero status belongs to this class.
DFTI_MEMORY_ERROR	Usually associated with memory allocation
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function)
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent
DFTI_MKL_INTERNAL_ERROR	Internal library error
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).

The `DftiErrorClass` function returns a non-zero value in C or the value of `.TRUE.` in Fortran if the status belongs to a predefined error class. To check whether a function call was successful, call `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See [Example "Using Status Checking Functions"](#) for an illustration of correct use of the status checking functions.

NOTE It is incorrect to directly compare a status with a predefined class.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorClass
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_8( Status, Error_Class )
LOGICAL some_actual_function_8
INTEGER, INTENT(IN) :: Status, Error_Class
END FUNCTION some_actual_function_8
END INTERFACE DftiErrorClass
```

```
/* C prototype */
MKL_LONG DftiErrorClass( MKL_LONG , MKL_LONG );
```

DftiErrorMessage

Generates an error message.

Syntax

Fortran:

```
error_message = DftiErrorMessage( status )
```

C:

```
error_message = DftiErrorMessage(status);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>status</code>	FORTRAN: INTEGER C: MKL_LONG	Completion status of a function.

Output Parameters

Name	Type	Description
<code>error_message</code>	FORTRAN: CHARACTER (LEN=DFTI_MAX_MESSAGE_LENGTH) C: Array of char	The character string with the error message.

Description

The error message function generates an error message character string. In Fortran, use a character string of length `DFTI_MAX_MESSAGE_LENGTH` as a target for the error message. In C, the function returns a pointer to a constant character string, that is, a character array with terminating '\0' character, and you do not need to free this pointer.

Example "Using Status Checking Function" shows how this function can be used.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorMessage
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
FUNCTION some_actual_function_9( Status )
CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) some_actual_function_9( Status )
INTEGER, INTENT(IN) :: Status
END FUNCTION some_actual_function_9
END INTERFACE DftiErrorMessage

/* C prototype */
char *DftiErrorMessage( MKL_LONG );
```

Configuration Settings

Each of the configuration parameters is identified by a named constant in the `MKL_DFTI` module. In C, these named constants have the enumeration type `DFTI_CONFIG_PARAM`.

All the Intel MKL FFT configuration parameters are readable. Some of them are read-only, while others can be set using the `DftiCreateDescriptor` or `DftiSetValue` function.

Values of the configuration parameters fall into the following groups:

- Values that have native data types. For example, the number of simultaneous transforms requested has an integer value, while the scale factor for a forward transform is a single-precision number.
- Values that are discrete in nature and are provided in the `MKL_DFTI` module as named constants. For example, the domain of the forward transform requires values to be named constants. In C, the named constants for configuration values have the enumeration type `DFTI_CONFIG_VALUE`.

Table "Configuration Parameters" summarises the information on configuration parameters, along with their types and values. For more details of each configuration parameter, see the subsection describing this parameter.

Configuration Parameters

Configuration Parameter	Type/Value	Comments
<i>Most common configuration parameters, no default, must be set explicitly by DftiCreateDescriptor</i>		
DFTI_PRECISION	Named constant DFTI_SINGLE or DFTI_DOUBLE	Precision of the computation.
DFTI_FORWARD_DOMAIN	Named constant DFTI_COMPLEX or DFTI_REAL	Type of the transform.
DFTI_DIMENSION	Integer scalar	Dimension of the transform.
DFTI_LENGTH	Integer scalar/array	Lengths of each dimension.
<i>Common configuration parameters, settable by DftiSetValue</i>		
DFTI_PLACEMENT	Named constant DFTI_INPLACE or DFTI_NOT_INPLACE	Defines whether the result overwrites the input data. Default value: DFTI_INPLACE.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor for the forward transform. Default value: 1.0. Precision of the value should be the same as defined by DFTI_PRECISION.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor for the backward transform. Default value: 1.0. Precision of the value should be the same as defined by DFTI_PRECISION.
DFTI_NUMBER_OF_USER_THREADS	Integer scalar	Number of threads that concurrently use the same descriptor to compute FFT.
DFTI_DESCRIPTOR_NAME	Character string	Assigns a name to a descriptor. Assumed length of the string is DFTI_MAX_NAME_LENGTH. Default value: empty string.
<i>Data layout configuration parameters for single and multiple transforms. Settable by DftiSetValue</i>		
DFTI_INPUT_STRIDES	Integer array	Defines the input data layout.
DFTI_OUTPUT_STRIDES	Integer array	Defines the output data layout.
DFTI_NUMBER_OF_TRANSFORMS	Integer scalar	Number of transforms. Default value: 1.
DFTI_INPUT_DISTANCE	Integer scalar	Defines the distance between input data sets for multiple transforms. Default value: 0.
DFTI_OUTPUT_DISTANCE	Integer scalar	Defines the distance between output data sets for multiple transforms. Default value: 0.

Configuration Parameter	Type/Value	Comments
DFTI_COMPLEX_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_REAL_REAL	Defines whether the real and imaginary parts of data for a complex transform are interleaved in one array or split in two arrays. Default value: DFTI_COMPLEX_COMPLEX.
DFTI_REAL_STORAGE	Named constant DFTI_REAL_REAL	Defines how real data for a real transform is stored. Only the DFTI_REAL_REAL value is supported.
DFTI_CONJUGATE_EVEN_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_COMPLEX_REAL	Defines whether the complex data in the backward domain of a real transform is stored as complex elements or as real elements. For the default value, see the detailed description.
DFTI_PACKED_FORMAT	Named constant DFTI_CCE_FORMAT, DFTI_CCS_FORMAT, DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT	Defines the layout of real elements in the backward domain of a one-dimensional or two-dimensional real transform.
<i>Advanced configuration parameters, settable by <code>DftiSetValue</code></i>		
DFTI_WORKSPACE	Named constant DFTI_ALLOW or DFTI_AVOID	Defines whether the library should prefer algorithms using additional memory. Default value: DFTI_ALLOW.
DFTI_ORDERING	Named constant DFTI_ORDERED or DFTI_BACKWARD_SCRAMBLED	Defines whether the result of a complex transform is ordered or permuted. Default value: DFTI_ORDERED.
<i>Read-Only configuration parameters</i>		
DFTI_COMMIT_STATUS	Named constant DFTI_UNCOMMITTED or DFTI_COMMITED	Readiness of the descriptor for computation.
DFTI_VERSION	String	Version of Intel MKL. Assumed length of the string is DFTI_VERSION_LENGTH.

DFTI_PRECISION

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

`DFTI_PRECISION` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

NOTE Fortran module `MKL_DFTI` also defines named constants `DFTI_SINGLE_R` and `DFTI_DOUBLE_R`, with the same semantics as `DFTI_SINGLE` and `DFTI_DOUBLE`, respectively. Do not use these constants to set the `DFTI_PRECISION` configuration parameter. Use them only as described in section `DftiCreateDescriptor`.

To better understand configuration of the precision of transforms, you can refer to these examples in your Intel MKL directory:

C: `./examples/dftc/source/basic_sp_complex_dft_1d.c`
`./examples/dftc/source/basic_dp_complex_dft_1d.c`

Fortran: `./examples/dftf/source/basic_sp_complex_dft_1d.f90`
`./examples/dftf/source/basic_dp_complex_dft_1d.f90`

See Also

[DFTI_FORWARD_DOMAIN](#)
[DFTI_DIMENSION, DFTI_LENGTHS](#)
[DftiCreateDescriptor](#)

DFTI_FORWARD_DOMAIN

The general form of a discrete Fourier transform is

$$Z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} W_{j_1, j_2, \dots, j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \dots, n_l-1$ ($l = 1, \dots, d$), where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the backward transform.

The Intel MKL implementation of the FFT algorithm, used for fast computation of discrete Fourier transforms, supports forward transforms on input sequences of two domains, as specified by the [DFTI_FORWARD_DOMAIN](#) configuration parameter: general complex-valued sequences ([DFTI_COMPLEX](#) domain) and general real-valued sequences ([DFTI_REAL](#) domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in [Table "Correspondence of Forward and Backward Domain"](#).

The conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x(k_1, k_2, \dots, k_d) = \text{conjugate}(x(n_1 - k_1, n_2 - k_2, \dots, n_d - k_d)),$$

where the index arithmetic is performed modulo respective size, that is,

$$x(\dots, expr_s, \dots) \equiv x(\dots, \text{mod}(expr_s, n_s), \dots),$$

and therefore

$$x(\dots, n_s, \dots) \equiv x(\dots, 0, \dots).$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in [DFTI_CONJUGATE_EVEN_STORAGE](#).

Correspondence of Forward and Backward Domain

Forward Domain	Implied Backward Domain
Complex (DFTI_COMPLEX)	Complex (DFTI_COMPLEX)
Real (DFTI_REAL)	Conjugate-even

[DFTI_FORWARD_DOMAIN](#) does not have a default value. Set it explicitly by calling the [DftiCreateDescriptor](#) function.

To better understand usage of the `DFTI_FORWARD_DOMAIN` configuration parameter, you can refer to these examples in your Intel MKL directory:

C:	<code>./examples/dftc/source/basic_sp_complex_dft_1d.c</code>
	<code>./examples/dftc/source/basic_sp_real_dft_1d.c</code>
Fortran:	<code>./examples/dftf/source/basic_sp_complex_dft_1d.f90</code>
	<code>./examples/dftf/source/basic_sp_real_dft_1d.f90</code>

See Also

[DFTI_PRECISION](#)

[DFTI_DIMENSION, DFTI_LENGTHS](#)

[DftiCreateDescriptor](#)

[DFTI_DIMENSION, DFTI_LENGTHS](#)

The dimension of the transform is a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For multi-dimensional (≥ 2) transform, the lengths of each of the dimensions are supplied in an integer array (`Integer` data type in Fortran and `MKL_LONG` data type in C).

`DFTI_DIMENSION` and `DFTI_LENGTHS` do not have a default value. To set them, use the `DftiCreateDescriptor` function and not the `DftiSetValue` function.

To better understand usage of the `DFTI_DIMENSION` and `DFTI_LENGTHS` configuration parameters, you can refer to basic examples of one-, two-, and three-dimensional transforms in your Intel MKL directory. Naming conventions for the examples are self-explanatory. For example, refer to these examples of single-precision two-dimensional transforms:

C:	<code>./examples/dftc/source/basic_sp_real_dft_2d.c</code>
	<code>./examples/dftc/source/basic_sp_complex_dft_2d.c</code>
Fortran:	<code>./examples/dftf/source/basic_sp_real_dft_2d.f90</code>
	<code>./examples/dftf/source/basic_sp_complex_dft_2d.f90</code>

[DftiSetValue](#)

[DFTI_PLACEMENT](#)

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. You can change that by setting it to `DFTI_NOT_INPLACE`.

NOTE The data sets have no common elements.

The following examples in your Intel MKL directory illustrate usage of the `DFTI_PLACEMENT` configuration parameter:

C:	<code>./examples/dftc/source/config_placement.c</code>
Fortran:	<code>./examples/dftf/source/config_placement.f90</code>

DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE

The forward transform and backward transform are each associated with a scale factor σ of its own having the default value of 1. You can specify the scale factors using one or both of the configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length n , you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be $1/n$, thus making the backward transform the inverse of the forward transform.

Set the scale factor configuration parameter using a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

NOTE For inquiry of the scale factor with the `DftiGetValue` function in C, the `config_val` parameter must have the same floating-point precision as the descriptor.

DFTI_NUMBER_OF_USER_THREADS

Use one of the following techniques to parallelize your application:

- a. You specify the parallel mode within the FFT module of Intel MKL instead of creating threads in your application. See *Intel MKL User's Guide* for more information on how to do this. See also [Example "Using Intel MKL Internal Threading Mode"](#).
- b. You create threads in the application yourself and have each thread perform all stages of FFT implementation, including descriptor initialization, FFT computation, and descriptor deallocation. In this case, each descriptor is used only within its corresponding thread. In this case, set single-threaded mode for Intel MKL. See [Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region"](#).
- c. You create threads in the application yourself after initializing all FFT descriptors. This implies that threading is employed for parallel FFT computation only, and the descriptors are released upon return from the parallel region. In this case, each descriptor is used only within its corresponding thread. You must explicitly set the single-threaded mode for Intel MKL, otherwise, the actual number of threads may differ from one, because the `DftiCommitDescriptor` function is not in a parallel region. See [Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread"](#).
- d. You create threads in the application yourself after initializing the only FFT descriptor. This implies that threading is employed for parallel FFT computation only, and the descriptor is released upon return from the parallel region. In this case, each thread uses the same descriptor. See [Example "Using Parallel Mode with a Common Descriptor"](#).

In cases "a", "b", and "c", listed above, set the parameter `DFTI_NUMBER_OF_USER_THREADS` to 1 (its default value), since each particular descriptor instance is used only in a single thread.

In case "d", use the `DftiSetValue()` function to set the `DFTI_NUMBER_OF_USER_THREADS` to the actual number of FFT computation threads, because multiple threads will be using the same descriptor. If this setting is not done, your program will work incorrectly or fail, since the descriptor contains individual data for each thread.

WARNING

- Avoid parallelizing your program and employing the Intel MKL internal threading simultaneously because this will slow down the performance. Note that in case "d" above, FFT computation is automatically initiated in a single-threading mode.
- Do not change the number of threads after the `DftiCommitDescriptor()` function completes FFT initialization.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For d -dimensional data set X defined by dimensions $N_1 \times N_2 \times \dots \times N_d$, the layout describes where a particular element $X(k_1, k_2, \dots, k_d)$ of the data set is located. The memory address of the element $X(k_1, k_2, \dots, k_d)$ is expressed by the formula

$$\begin{aligned} \text{address of } X(k_1, k_2, \dots, k_d) &= \text{address of } X(0, 0, \dots, 0) + \text{offset} \\ &= \text{address of } X(0, 0, \dots, 0) + s_0 + k_1 * s_1 + k_2 * s_2 + \dots + k_d * s_d \end{aligned}$$

where s_0 is the displacement and s_1, \dots, s_d are generalized strides. The configuration parameters [DFTI_INPUT_STRIDES](#) and [DFTI_OUTPUT_STRIDES](#) enable you to get and set these values. The configuration value is an array of values (s_0, s_1, \dots, s_d) of INTEGER data type in Fortran and MKL_LONG data type in C.

The offset is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the [DFTI_FORWARD_DOMAIN](#), [DFTI_COMPLEX_STORAGE](#), and [DFTI_CONJUGATE_EVEN_STORAGE](#) configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#):

Assumed Element Types of the Input/Output Data

Descriptor Configuration	Element Type in the Forward Domain	Element Type in the Backward Domain
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX	Complex	Complex
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX	Real	Complex

The [DFTI_INPUT_STRIDES](#) configuration parameter defines the layout of the input data, while the element type is defined by the forward domain for the [DftiComputeForward](#) function and by the backward domain for the [DftiComputeBackward](#) function. The [DFTI_OUTPUT_STRIDES](#) configuration parameter defines the layout of the output data, while the element type is defined by the backward domain for the [DftiComputeForward](#) function and by the forward domain for [DftiComputeBackward](#) function.

NOTE The [DFTI_INPUT_STRIDES](#) and [DFTI_OUTPUT_STRIDES](#) configuration parameters define the layout of input and output data, and not the forward-domain and backward-domain data. If the data layouts in forward domain and backward domain differ, set [DFTI_INPUT_STRIDES](#) and [DFTI_OUTPUT_STRIDES](#) explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_STRIDES` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_STRIDES` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the first elements on input and output must coincide in each dimension.

The FFT interface supports both positive and negative stride values. If you use negative strides, set the displacement of the data as follows:

$$s_0 = \sum_{i=1}^d (N_i - 1) \cdot \max(-s_i, 0).$$

The default setting of strides in a general multi-dimensional case assumes that the array that contains the data has no padding. The order of the strides depends on the programming language. For example:

```
/* C/C++ */
MKL_LONG dims[] = { nd, ..., n2, n1 };
DftiCreateDescriptor( &hand, precision, domain, d, dims );
// The above call assumes data declaration: type X[nd]...[n2][n1]
// Default strides are { 0, nd*...*n2*n1, ..., n2*n1, n1, 1 }

! Fortran
INTEGER :: dims(d) = [n1, n2, ..., nd]
status = DftiCreateDescriptor( hand, precision, domain, d, dims )
! The above call assumes data declaration: type X(n1,n2,...,nd)
! Default strides are [ 0, 1, n1, n1*n2, ..., n1*n2*...*nd]
```

Note that in case of a real FFT (`DFTI_FORWARD_DOMAIN=DFTI_REAL`), where different data layouts in the backward domain are available (see [DFTI_PACKED_FORMAT](#)), the default value of the strides is not intuitive for the recommended CCE format (configuration setting

`DFTI_CONJUGATE EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`). In case of an *in-place* real transform with the CCE format, set the strides explicitly, as follows:

```
/* C/C++ */
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG rstrides[] = { 0, 2*nd*...*n2*(n1/2+1), ..., 2*n2*(n1/2+1), 2*(n1/2+1), 1 };
MKL_LONG cstrides[] = { 0, nd*...*n2*(n1/2+1), ..., n2*(n1/2+1), (n1/2+1), 1 };
DftiCreateDescriptor( &hand, precision, DFTI_REAL, d, dims );
DftiSetValue(hand, DFTI_CONJUGATE EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
// Set the strides appropriately for forward/backward transform

! Fortran
INTEGER :: dims(d) = [n1, n2, ..., nd]
INTEGER :: rstrides(1+d) = [0, 1, 2*(n1/2+1), 2*(n1/2+1)*n2, ... ]
INTEGER :: cstrides(1+d) = [0, 1, (n1/2+1), (n1/2+1)*n2, ... ]
status = DftiCreateDescriptor( hand, precision, domain, d, dims )
status = DftiSetValue( hand, DFTI_CONJUGATE EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
! Set the strides appropriately for forward/backward transform
```

To better understand configuration of strides, you can also refer to these examples in your Intel MKL directory:

DFTI_NUMBER_OF_TRANSFORMS

In some situations, you may need to perform a number of identical FFTs. You can do this with a single call to a `DftiCompute*` function if the value of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter is set to the actual number of the transforms. The default value of this parameter is one. You can set this parameter to a positive integer value using the `Integer` data type in Fortran and `MKL_LONG` data type in C. When setting the number of transforms to a value greater than one, you also need to specify the distance between the input and output data sets using one of the `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` configuration parameters or both.

- The data sets to be transformed must not have common elements.
- All the sets of data must be located within the same memory block.

The following examples in your Intel MKL directory illustrate usage of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter:

C:	<code>./examples/dftc/source/config_number_of_transforms.c</code>
Fortran:	<code>./examples/dftf/source/config_number_of_transforms.f90</code>

[FFT Computation Functions](#)
[DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE](#)
[DftiSetValue](#)

DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE

The FFT interface in Intel MKL enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, `DFTI_INPUT_DISTANCE` for input data or `DFTI_OUTPUT_DISTANCE` for output data, specifies the distribution. The configuration setting is a value of `INTEGER` data type in Fortran and `MKL_LONG` data type in C.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see [DFTI_NUMBER_OF_TRANSFORMS](#)).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#).

NOTE The configuration parameters `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` define the distance within input and output data, and not within the forward-domain and backward-domain data. If the distances in the forward and backward domains differ, set `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_DISTANCE` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_DISTANCE` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the data sets on input and output must coincide.

The following examples illustrate setting of the `DFTI_INPUT_DISTANCE` configuration parameter:

```

MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG distance = nd*...*n2*n1;
DftiCreateDescriptor( &hand, precision, DFTI_COMPLEX, d, dims );
DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, (MKL_LONG)howmany );
DftiSetValue( hand, DFTI_INPUT_DISTANCE, distance );

! Fortran
INTEGER :: dims(d) = [n1, n2, ..., nd]
INTEGER :: distance = n1*n2*...*nd
status = DftiCreateDescriptor( hand, precision, DFTI_COMPLEX, d, dims)
status = DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, howmany )
status = DftiSetValue( hand, DFTI_INPUT_DISTANCE, distance );

```

To better understand configuration of the distances, you can also refer to these examples in your Intel MKL directory:

C:	<code>./examples/dftc/source/config_number_of_transforms.c</code>
Fortran:	<code>./examples/dftf/source/config_number_of_transforms.f90</code>

[DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE](#)

Depending on the value of the `DFTI_FORWARD_DOMAIN` configuration parameter, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see [DFTI_INPUT_STRIDES](#), [DFTI_OUTPUT_STRIDES](#)). For multiple transforms, all sets of data should be located within the same memory block, and the data sets should be placed at the same distance from each other (see [DFTI_NUMBER_OF_TRANSFORMS](#) and [DFTI_INPUT_DISTANCE](#), [DFTI_OUTPUT_DISTANCE](#)).

TIP In C/C++, avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

[FFT Examples](#) demonstrate the usage of storage formats in both C and Fortran.

[DFTI_COMPLEX_STORAGE: storage schemes for a complex domain](#)

For the `DFTI_COMPLEX` forward domain, both input and output sequences belong to a complex domain. In this case, the configuration parameter `DFTI_COMPLEX_STORAGE` can have one of the two values:

`DFTI_COMPLEX_COMPLEX` (default) or `DFTI_REAL_REAL`.

NOTE In the Intel MKL FFT interface, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With `DFTI_COMPLEX_COMPLEX` storage, complex-valued data sequences are referenced by a single complex parameter (array) `AZ` so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m -th d -dimensional sequence is located at $AZ[m * \text{distance} + \text{stride}_0 + k_1 * \text{stride}_1 + k_2 * \text{stride}_2 + \dots + k_d * \text{stride}_d]$ as a structure consisting of the real and imaginary parts.

The following examples illustrate usage of the `DFTI_COMPLEX_COMPLEX` storage:

```

! Fortran
complex :: AZ(N1,N2,N3,M)    ! sizes and number of transforms
...

```

```
! on input: Z{k1,k2,k3,m} = AZ(k1,k2,k3,m)
status = DftiComputeForward( desc, AZ(:,1,1,1) )
! on output: Z{k1,k2,k3,m} = AZ(k1,k2,k3,m)
```

```
// C/C++
complex *AZ = malloc( N1*N2*N3*M * sizeof(AZ[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AZ );
// on output: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

With the `DFTI_REAL_REAL` storage, complex-valued data sequences are referenced by two real parameters `AR` and `AI` so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m -th sequence is computed as $AR[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*strided] + \sqrt{-1} * AI[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*strided]$.

The following examples illustrate usage of the `DFTI_REAL_REAL` storage:

```
! Fortran
real :: AR(N1,N2,N3,M), AI(N1,N2,N3,M)
...
! on input: Z{k1,k2,k3,m} = cmplx(AR(k1,k2,k3,m),AI(k1,k2,k3,m))
status = DftiComputeForward( desc, AR(:,1,1,1), AI(:,1,1,1) )
! on output: Z{k1,k2,k3,m} = cmplx(AR(k1,k2,k3,m),AI(k1,k2,k3,m))
```

```
// C/C++
float *AR = malloc( N1*N2*N3*M * sizeof(AR[0]) );
float *AI = malloc( N1*N2*N3*M * sizeof(AI[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AR, AI );
// on output: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

DFTI_REAL_STORAGE: storage schemes for a real domain

The Intel MKL FFT interface supports only one configuration value for this storage scheme: `DFTI_REAL_REAL`. With the `DFTI_REAL_REAL` storage, real-valued data sequences in a real domain are referenced by one real parameter `AR` so that real-valued element of the m -th sequence is located as $AR[m*distance + stride_0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*strided]$.

DFTI_CONJUGATE_EVEN_STORAGE: storage scheme for a conjugate-even domain

The Intel MKL FFT interface supports two configuration values for this parameter: `DFTI_COMPLEX_REAL` (default) and `DFTI_COMPLEX_COMPLEX`. In both cases, the conjugate-even symmetry of the data enables storing only about a half of the whole mathematical result, so that one part of it can be directly referenced in the memory while the other part can be reconstructed depending on the selected storage configuration.

With the `DFTI_COMPLEX_REAL` storage, the complex-valued data sequences in the conjugate-even domain can be reconstructed as described in section [DFTI_PACKED_FORMAT](#).

Important Although `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL` is the default setting for the `DFTI_REAL` forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms and will be deprecated in future.

With the `DFTI_COMPLEX_COMPLEX` storage, the complex-valued data sequences in the conjugate-even domain are referenced by one complex parameter `AZ` so that a complex-valued element z_{k_1, k_2, \dots, k_d} of the m -th sequence can be referenced or reconstructed as described below.

Important Use the `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX` configuration setting, which will become the default in future. This setting is supported for all transform ranks, provides a uniform pattern for reconstructing the entire conjugate-even sequence from the part of it that is actually stored, and is compatible with data layouts supported by other FFT libraries, such as FFTW. This storage scheme disregards the setting of `DFTI_PACKED_FORMAT`.

Consider a d-dimensional real-to-complex transform

$$Z_{k_1, k_2, \dots, k_d} \equiv \sum_{n_1=0}^{N_1-1} \cdots \sum_{n_d=0}^{N_d-1} R_{n_1, n_2, \dots, n_d} e^{\frac{-2\pi i}{N_1} k_1 \cdot n_1} \cdots e^{\frac{-2\pi i}{N_d} k_d \cdot n_d}$$

Because the input sequence `R` is real-valued, the mathematical result `Z` has conjugate-even symmetry:

$$z_{k_1, k_2, \dots, k_d} = \text{conjugate}(z_{N_1-k_1, N_2-k_2, \dots, N_d-k_d}),$$

where index arithmetic is performed modulo the length of the respective dimension. Obviously, the first element of the result is real-valued:

$$z_{0, 0, \dots, 0} = \text{conjugate}(z_{0, 0, \dots, 0}).$$

For dimensions with even lengths, the other elements are real-valued too. For example, if N_s is even,

$$z_{0, 0, \dots, N_s/2, 0, \dots, 0} = \text{conjugate}(z_{0, 0, \dots, N_s/2, 0, \dots, 0}).$$

With the conjugate-even symmetry, approximately a half of the result suffices to fully reconstruct it. For an arbitrary dimension h , it suffices to store elements $z_{k_1, \dots, k_h, \dots, k_d}$ for the following indices:

- $k_h = 0, \dots, [N_h/2]$
- $k_i = 0, \dots, N_i - 1$, where $i = 1, \dots, d$ and $i \neq h$

The symmetry property enables reconstructing the remaining elements: for $k_h = [N_h/2] + 1, \dots, N_h - 1$. In the Intel MKL FFT interface, the halved dimension is the first dimension in Fortran and the last dimension in C/C++.

The following examples illustrate usage of the `DFTI_COMPLEX_COMPLEX` storage for a conjugate-even domain:

```
! Fortran
real :: AR(N1,N2,M)           ! Array containing values of R
complex :: AZ(N1/2+1,N2,M)     ! Array containing values of Z
...
! on input: R{k1,k2,m} = AR(k1,k2,m)
status = DftiComputeForward( desc, AR(:,1,1), AZ(:,1,1) )
! on output:
! for k1=1 ... N1/2+1: Z{k1,k2,m} = AZ(k1,k2,m)
! for k1=N1/2+2 ... N1: Z{k1,k2,m} = conj(AZ(mod(N1-k1+1,N1)+1,mod(N2-k2+1,N2)+1,m))
```

```
// C/C++
float *AR = malloc( N1*N2*M * sizeof(AR[0]) );
complex *AZ = malloc( N1*(N2/2+1)*M * sizeof(AZ[0]) );
MKL_LONG is[3], os[3], idist, odist; // input and output strides and distance
...
// on input: R{k1,k2,m}
// = AR[is[0] + k1*is[1] + k2*is[2] + m*idist]
status = DftiComputeForward( desc, R, C );
// on output:
```

```
// for k2=0..N2/2: Z{k1,k2,m} = AZ[os[0]+k1*os[1]+k2*os[2]+m*odist]
// for k2=N2/2+1..N2-1: Z{k1,k2,m} = conj(AZ[os[0]+(N1-k1)%N1*os[1]
//                                         +(N2-k2)%N2*os[2]+m*odist])
//
```

For the backward transform, the input and output parameters and layouts exchange roles: set the strides describing the layout in the backward/forward domain as input/output strides, respectively. For example:

```
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, fwd_domain_strides )
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, bwd_domain_strides )
status = DftiCommitDescriptor( desc )
status = DftiComputeForward( desc, ... )

...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, bwd_domain_strides )
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, fwd_domain_strides )
status = DftiCommitDescriptor( desc )
status = DftiComputeBackward( desc, ... )
```

Important For in-place transforms, ensure the first element of the input data has the same address as the first element of the output data for each dimension.

DFTI_PACKED_FORMAT

The result of the forward transform of real data is a conjugate-even sequence. Due to the symmetry property, only a part of the complex-valued sequence is stored in memory. The complex-valued sequence can be interpreted as a real-valued sequence and packed as real data. The `DFTI_PACKED_FORMAT` configuration parameter defines how the data is packed and applies only when the `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameter has the value of `DFTI_COMPLEX_REAL`, which means "a complex-valued sequence is stored in a real-valued array". With this storage scheme many of the complex-valued elements of the result cannot be referenced directly in the memory, but can be reconstructed by locating their real and imaginary parts in the packed result.

NOTE Although `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL` is the default setting for the `DFTI_REAL` forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms, is incompatible with storage schemes of other FFT libraries, and will be deprecated in future.

The Intel MKL FFT interface supports the following packed formats:

- [DFTI_CCS_FORMAT](#)
- [DFTI_PACK_FORMAT](#)
- [DFTI_PERM_FORMAT](#)

NOTE `DFTI_CCE_FORMAT`, the remaining value of `DFTI_PACKED_FORMAT`, describes the storage of a complex-valued conjugate-even sequence in complex-valued arrays and applies when `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX` (see [DFTI_CONJUGATE_EVEN_STORAGE](#) for details). The `DFTI_PACKED_FORMAT` configuration parameter does not apply in this case.

DFTI_CCS_FORMAT for One-dimensional Transforms

The following figure illustrates the storage of a one-dimensional (1D) size- N conjugate-even sequence in a real array for the CCS, PACK, and PERM packed formats. The CCS format requires an array of size $N+2$, while the other formats require an array of size N . Zero-based indexing is used.

Storage of a 1D Size- N Conjugate-even Sequence in a Real Array

$n =$	0	1	2	3	...	$2L-2$	$2L-1$	$2L$	$2L+1$	$2L+2$

The real and imaginary parts of the complex-valued conjugate-even sequence z_k are located in a real-valued array AC as illustrated by figure "Storage of a 1D Size- N Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
! Fortran
real :: AR(N), AC(N+2)
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT )
...
! on input: R{k} = AR(k)
status = DftiComputeForward( desc, AR, AC ) ! real-to-complex FFT
! on output:
! for k=1 ... N/2+1: Z{k} = cmplx( AC(1 + (2*(k-1)+0)),
!                                AC(1 + (2*(k-1)+1)) )
! for k=N/2+2 ... N: Z{k} = cmplx( AC(1 + (2*mod(N-k+1,N)+0)),
!                                -AC(1 + (2*mod(N-k+1,N)+1)))
```

```
// C/C++
float *AR; // malloc( sizeof(float)*N )
float *AC; // malloc( sizeof(float)*(N+2) )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT );
...
// on input: R{k} = AR[k]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output:
// for k=0..N/2: Z{k} = AC[2*k+0] + I*AC[2*k+1]
// for k=N/2+1..N-1: Z{k} = AC[2*(N-k)%N + 0] - I*AC[2*(N-k)%N + 1]
```

DFTI_CCS_FORMAT for Two-dimensional Transforms

The following figure illustrates the storage of a two-dimensional (2D) M -by- N conjugate-even sequence in a real array for the CCS packed format. This format requires an array of size $(M+2)$ -by- $(N+2)$. Row-major layout and zero-based indexing are used. Different colors mark logically separate parts of the result. "n/u" means "not used".

DFTI_WORKSPACE

The computation step for some FFT algorithms requires a scratch space for permutation or other purposes. To manage the use of the auxiliary storage, Intel MKL enables you to set the configuration parameter `DFTI_WORKSPACE` with the following values:

<code>DFTI_ALLOW</code>	(default) Permits the use of the auxiliary storage.
<code>DFTI_AVOID</code>	Instructs Intel MKL to avoid using the auxiliary storage if possible.

[DftiSetValue](#)

DFTI_COMMIT_STATUS

The `DFTI_COMMIT_STATUS` configuration parameter indicates whether the descriptor is ready for computation. The parameter has two possible values:

<code>DFTI_UNCOMMITTED</code>	Default value, set after a successful call of <code>DftiCreateDescriptor</code> .
<code>DFTI_COMMITED</code>	The value after a successful call to <code>DftiCommitDescriptor</code> .

A computation function called with an uncommitted descriptor returns an error.

You cannot directly set this configuration parameter in a call to `DftiSetValue`, but a change in the configuration of a committed descriptor may change the commit status of the descriptor to `DFTI_UNCOMMITTED`.

DFTI_ORDERING

Some FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying an FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus using scrambled data is acceptable if it leads to better performance. The following options are available in Intel MKL:

- `DFTI_ORDERED`: Forward transform data ordered, backward transform data ordered (default option).
- `DFTI_BACKWARD_SCRAMBLED`: Forward transform data ordered, backward transform data scrambled.

Table "Scrambled Order Transform" tabulates the effect of this configuration setting.

Scrambled Order Transform

	DftiComputeForward	DftiComputeBackward
DFTI_ORDERING	Input → Output	Input → Output
DFTI_ORDERED	ordered → ordered	ordered → ordered
DFTI_BACKWARD_SCRAMBLED	ordered → scrambled	scrambled → ordered

NOTE The word "scrambled" in this table means "permit scrambled order if possible". In some situations permitting out-of-order data gives no performance advantage and an implementation may choose to ignore the suggestion.

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

NOTE These functions are available only for the Linux* and Windows* operating systems.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL [FFT functions](#), described earlier in this chapter. Refer there for details not explained in this section.

[Table "Cluster FFT Functions in Intel MKL"](#) lists cluster FFT functions implemented in Intel MKL:

Cluster FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptorDM	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	

Function Name	Operation
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The cluster FFT functions described later in this section are provided with Fortran and C interfaces. Fortran stands for Fortran 95.

Cluster FFT computation is performed by `DftiComputeForwardDM` and `DftiComputeBackwardDM` functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates local part of the input data, i.e. some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` in C/C++ or `MPI_INIT` in Fortran (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling `DftiCreateDescriptorDM`.
3. Specify one of several values of configuration parameters by one or more calls to `DftiSetValueDM`.
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling `DftiGetValueDM`.
5. Initialize the descriptor for the FFT computation by calling `DftiCommitDescriptorDM`.
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see [Distributing Data among Processes](#).)
7. Compute the transform by calling `DftiComputeForwardDM` or `DftiComputeBackwardDM`.
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling `DftiFreeDescriptorDM`.
10. Finalize communication through MPI by calling `MPI_Finalize` in C/C++ or `MPI_FINALIZE` in Fortran (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the "Examples for Cluster FFT Functions" section in Appendix C illustrate cluster FFT computations.

Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order in C/C++ and in the column-major order in Fortran. For example, a two-dimensional matrix A of size (m, n) is stored in a vector B of size $m \times n$ so that

- $B[i \cdot n + j] = A[i][j]$ in C/C++ ($i=0, \dots, m-1, j=0, \dots, n-1$)
- $B((j-1) \cdot m + i) = A(i, j)$ in Fortran ($i=1, \dots, m, j=1, \dots, n$)

NOTE Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with Lengths= $(m, n, 1)$ can be computed over an array $Ar[m][n][1]$ in C/C++ or $AR(m, n, 1)$ in Fortran.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able do this, see sections below on how the virtual global array is composed of the local ones.

Multidimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C and the last one in Fortran. If the global array is two-dimensional, in C, it gives each process several consecutive rows. The term "rows" will be used regardless of the array dimension and programming language. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size (11,15,12), the processes may store local arrays of sizes (6,15,12) and (5,15,12), respectively.

If p is the number of MPI processes and the matrix of a transform to be computed has size (m, n, l) , in C, each MPI process works with local data array of size (m_q, n, l) , where $\sum m_q = m$, $q=0, \dots, p-1$. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the [DftiGetValueDM](#) function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If `A` is a global array and `L` is the appropriate local array, then
 - `L[i][j][k]=A[i+cdft_local_start_x][j][k]`, where $i=0, \dots, m_q-1$, $j=0, \dots, n-1$, $k=0, \dots, l-1$ for C/C++
 - `L(i,j,k)=A(i,j,k+cdft_local_start_x-1)`, where $i=1, \dots, m$, $j=1, \dots, n$, $k=1, \dots, l_q$ for Fortran.

[Example "2D Out-of-place Cluster FFT Computation" in Appendix C](#) shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the [DftiGetValueDM](#) function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in [Table "Data Distribution Configuration Parameters for 1D Transforms"](#):

Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	<code>CDFT_LOCAL_NX</code>	<code>CDFT_LOCAL_OUT_NX</code>
Elements shift in input array	<code>CDFT_LOCAL_START_X</code>	<code>CDFT_LOCAL_OUT_START_X</code>
Number of elements in output array	<code>CDFT_LOCAL_OUT_NX</code>	<code>CDFT_LOCAL_NX</code>

Meaning of the Parameter	Forward Transform	Backward Transform
Elements shift in output array	CDFT_LOCAL_OUT_START_X	CDFT_LOCAL_START_X

Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table "Settable configuration Parameters"](#)), it must have the same size as the local arrays. [Example "1D In-place Cluster FFT Computations"](#) in Appendix C illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation effected with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory: `examples/cdftc/source/cdft_example_support.c` for C/C++ and `examples/cdftf/source/cdft_example_support.f90` for Fortran.

Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions in C/C++ or of the last two dimensions in Fortran must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

Cluster FFT Interface

To use the cluster FFT functions, you need to access the module `MKL_CDFT` through the "use" statement in Fortran; or access the header file `mkl_cdft.h` through "include" in C/C++.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR_DM`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- Fortran:

```
INCLUDE "mpif.h"
(for some MPI versions, "mpif90.h" header may be used instead).
• C/C++:
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel MKL:

1. **Descriptor Manipulation.** There are three functions in this category. The [DftiCreateDescriptorDM](#) function creates an FFT descriptor whose storage is allocated dynamically. The [DftiCommitDescriptorDM](#) function "commits" the descriptor to all its settings. The [DftiFreeDescriptorDM](#) function frees up the memory allocated for the descriptor.
2. **FFT Computation.** There are two functions in this category. The [DftiComputeForwardDM](#) function performs the forward FFT computation, and the [DftiComputeBackwardDM](#) function performs the backward FFT computation.
3. **Descriptor Configuration.** There are two functions in this category. The [DftiSetValueDM](#) function sets one specific configuration value to one of the many configuration parameters. The [DftiGetValueDM](#) function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

DftiCreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, size)
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, sizes)
```

C:

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size);
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes);
```

Include Files

- FORTRAN 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

<i>comm</i>	MPI communicator, e.g. <code>MPI_COMM_WORLD</code> .
<i>v1</i>	Precision of the transform.
<i>v2</i>	Type of the forward domain. Must be <code>DFTI_COMPLEX</code> for complex-to-complex transforms or <code>DFTI_REAL</code> for real-to-complex transforms.
<i>dim</i>	Dimension of the transform.
<i>size</i>	Length of the transform in a one-dimensional case.
<i>sizes</i>	Lengths of the transform in a multi-dimensional case.

Output Parameters

<code>handle</code>	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.
---------------------	---

Description

This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created descriptor. This function is slightly different from the "initialization" function [DftiCommitDescriptorDM](#) in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function [DftiSetValueDM](#).

The value of the parameter `v1` is specified through named constants `DFTI_SINGLE` and `DFTI_DOUBLE`. It corresponds to precision of input data, output data, and computation. A setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The parameter `dim` is a simple positive integer indicating the dimension of the transform.

In C/C++, for one-dimensional transforms, length is a single integer value of the parameter `size` having type `MKL_LONG`; for multi-dimensional transforms, length is supplied with the parameter `sizes`, which is an array of integers having type `MKL_LONG`. In Fortran, length is an integer or an array of integers.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. In this case, the pointer to the created descriptor handle is stored in `handle`. If the function fails, it returns a value of another error class constant

Interface and Prototype

```

! Fortran Interface

INTERFACE DftiCreateDescriptorDM
    INTEGER(4) FUNCTION DftiCreateDescriptorDMn(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L(*)
    END FUNCTION

    INTEGER(4) FUNCTION DftiCreateDescriptorDM1(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L
    END FUNCTION

END INTERFACE

/*
 * C/C++ prototype */
MKL_LONG DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
    enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,MKL_LONG,...);

```

DftiCommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptorDM(handle)
```

C:

```
status = DftiCommitDescriptorDM(handle);
```

Include Files

- FORTRAN 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
---------------	--

Description

The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The `DftiCommitDescriptorDM` function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation](#)).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCommitDescriptorDM
    INTEGER(4) FUNCTION DftiCommitDescriptorDM(handle);
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
    END FUNCTION
END INTERFACE

/*
 * C/C++ prototype */
MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

DftiFreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptorDM(handle)
```

C:

```
status = DftiFreeDescriptorDM(&handle);
```

Include Files

- FORTRAN 90: mkl_cdft.f90
 - C: mkl_cdft.h

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

Output Parameters

handle The descriptor handle. Memory allocated for the handle is released on output.

Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiFreeDescriptorDM
    INTEGER(4) FUNCTION DftiFreeDescriptorDM(handle)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
    END FUNCTION
END INTERFACE

/*
*/
/* C/C++ prototype */
MKL LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM HANDLE *handle);
```

FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

DftiComputeForwardDM

Computes the forward FFT.

Syntax

Fortran:

```
Status = DftiComputeForwardDM(handle, in_X, out_X)
Status = DftiComputeForwardDM(handle, in_out_X)
```

C:

```
status = DftiComputeForwardDM(handle, in_X, out_X);
status = DftiComputeForwardDM(handle, in_out_X);
```

Include Files

- FORTRAN 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

<i>handle</i>	The descriptor handle.
<i>in_X, in_out_X</i>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

<i>out_X, in_out_X</i>	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.
------------------------	--

Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data Among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```

        COMPLEX(8), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMi

    INTEGER(4) FUNCTION DftiComputeForwardDMs(h, in_X, out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_X, out_X
    END FUNCTION DftiComputeForwardDMs

    INTEGER(4) FUNCTION DftiComputeForwardDMIs(h, in_out_X)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        COMPLEX(4), DIMENSION(*) :: in_out_X
    END FUNCTION DftiComputeForwardDMIs

END INTERFACE

/*
 * C/C++ prototype */
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);

```

DftiComputeBackwardDM

Computes the backward FFT.

Syntax

Fortran:

```

Status = DftiComputeBackwardDM(handle, in_X, out_X)
Status = DftiComputeBackwardDM(handle, in_out_X)

```

C:

```

status = DftiComputeBackwardDM(handle, in_X, out_X);
status = DftiComputeBackwardDM(handle, in_out_X);

```

Include Files

- FORTRAN 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

<code>handle</code>	The descriptor handle.
<code>in_X, in_out_X</code>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

<code>out_X, in_out_X</code>	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.
------------------------------	--

Description

The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);

```

Descriptor Configuration Functions

There are two functions in this category: the value setting function `DftiSetValueDM` sets one particular configuration parameter to an appropriate value, the value getting function `DftiGetValueDM` reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) subsection in the "FFT Functions" section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `MKL_LONG` in C/C++ and `INTEGER(4)` in Fortran. The exact type of the configuration parameters being floating-point scalars is `float` or `double` in C/C++ and `REAL(4)` or `REAL(8)` in Fortran. The configuration parameters whose values are named constants have the `enum` type in C/C++ and `INTEGER` in Fortran. They are defined in the `mkl_cdft.h` header file in C/C++ and `MKL_CDFT` module in Fortran.

Names of the configuration parameters specific to the cluster FFT interface have prefix `CDFT`.

DftiSetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValueDM (handle, param, value)
```

C:

```
status = DftiSetValueDM (handle, param, value);
```

Include Files

- FORTRAN 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be set up in the descriptor handle. See Table "Settable Configuration Parameters" for the list of available parameters.
<i>value</i>	Value of the parameter.

Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of each setting and for possible values of the parameters whose values are named constants.

Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.	1.0
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.	1.0
DFTI_PLACEMENT	Named constant	Placement of the computation result.	DFTI_INPLACE
DFTI_ORDERING	Named constant	Scrambling of data order.	DFTI_ORDERED
DFTI_WORKSPACE	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).
DFTI_PACKED_FORMAT	Named constant	Packed format, real data.	<ul style="list-style-type: none"> DFTI_PERM_FORMAT — default and the only available value for one-dimensional transforms

Parameter Name	Data Type	Description	Default Value
DFTI_TRANSPOSE	Named constant	This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is DFTI_NONE, the data is located in a usual manner described in this manual. If the value is DFTI_ALLOW, the last (first) global transposition is not performed for a forward (backward) transform.	<ul style="list-style-type: none"> • DFTI_CCE_FORMAT — default and the only available value for multi-dimensional transforms DFTI_NONE

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

    END FUNCTION

END INTERFACE

/*
 * C/C++ prototype */
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);

```

DftiGetValueDM

Gets the value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValueDM(handle, param, value)
```

C:

```
status = DftiGetValueDM(handle, param, &value);
```

Include Files

- FORTRAN 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

param Name of a parameter to be retrieved from the descriptor. See [Table "Retrievable Configuration Parameters"](#) for the list of available parameters.

Output Parameters

value Value of the parameter.

Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table "Configuration Parameters"](#) and relevant subsections of the [Configuration Settings](#) section.

Retrievable Configuration Parameters

Parameter Name	Data Type	Description
DFTI_PRECISION	Named constant	Precision of computation, input data and output data.
DFTI_DIMENSION	Integer scalar	Dimension of the transform
DFTI_LENGTHS	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.
DFTI_PLACEMENT	Named constant	Placement of the computation result.
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms, has the value of DFTI_COMPLEX or DFTI_REAL.
DFTI_ORDERING	Named constant	Scrambling of data order.

Parameter Name	Data Type	Description
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes .
CDFT_LOCAL_NX	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes .
CDFT_LOCAL_OUT_X_START	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes .
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes .

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Interface and Prototype

```

! Fortran Interface

INTERFACE DftiGetValueDM

    INTEGER(4) FUNCTION DftiGetValueDM(h, p, v)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
        INTEGER(4) :: p, v

MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);

```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns DFTI_NO_ERROR if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix "CDFT" in names. [Table "Error Codes that Cluster FFT Functions Return"](#) lists error codes that the cluster FFT functions may return.

[Error Codes that Cluster FFT Functions Return](#)

Named Constants	Comments
DFTI_NO_ERROR	No error.
DFTI_MEMORY_ERROR	Usually associated with memory allocation.

Named Constants	Comments
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters.
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters.
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors.
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation.
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent.
DFTI_MKL_INTERNAL_ERROR	Internal library error.
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).
CDFT_SPREAD_ERROR	Data cannot be distributed (For more information, see Distributing Data among Processes .)
CDFT_MPI_ERROR	MPI error. Occurs when calling MPI.

PBLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the PBLAS (Parallel Basic Linear Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using in vector-vector, matrix-vector, and matrix-matrix operations to simplify the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- [PBLAS Level 1 Routines](#) (distributed vector-vector operations)
- [PBLAS Level 2 Routines](#) (distributed matrix-vector operations)
- [PBLAS Level 3 Routines](#) (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by the routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to a character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

NOTE PBLAS routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. The Intel MKL version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see [Intel® MKL Release Notes](#) and [Intel® MKL User's Guide](#).

For full reference on PBLAS routines and related information, see http://www.netlib.org/scalapack/html/pblas_qref.html.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. [Table "Content of the array descriptor for dense matrices"](#) gives an example of an array descriptor structure.

Content of Array Descriptor for Dense Matrices

Array Element #	Name	Definition
1	<code>dtype</code>	Descriptor type (=1 for dense matrices)
2	<code>ctxt</code>	BLACS context handle for the process grid

Array Element #	Name	Definition
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>l1d</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr()* and *LOCc()*, respectively. To compute these numbers, you can use the ScaLAPACK tool routine *numroc*.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray *sub(A)*, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of <i>sub(A)</i>
<i>n</i>	The number of columns of <i>sub(A)</i>
<i>a</i>	A pointer to the local array containing the entire global array <i>A</i>
<i>ia</i>	The row index of <i>sub(A)</i> in the global array
<i>ja</i>	The column index of <i>sub(A)</i> in the global array
<i>desca</i>	The array descriptor for the global array <i>A</i>

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see http://www.netlib.org/scalapack/html/pblas_qref.html).

Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see [Routine Naming Conventions in Chapter 2](#)). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter *p* that stands for "parallel".

The Intel MKL PBLAS routine names have the following structure:

```
p <character> <name> <mod> ( )
```

The *<character>* field indicates the Fortran data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision
i	integer

Some routines and functions can have combined character codes, such as *sc* or *dz*.

For example, the function *pscasum* uses a complex input array and returns a real value.

The *<name>* field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines *p?dot*, *p?swap*, *p?copy* compute a vector dot product, vector swap, and a copy vector, respectively.

In PBLAS level 2 and 3, *<name>* reflects the matrix argument type:

ge	general matrix
sy	symmetric matrix
he	Hermitian matrix
tr	triangular matrix

In PBLAS level 3, the *<name>=tran* indicates the transposition of the matrix.

The `<mod>` field, if present, provides additional details of the operation. The PBLAS level 1 names can have the following characters in the `<mod>` field:

c	conjugated vector
u	unconjugated vector

The PBLAS level 2 names can have the following additional characters in the `<mod>` field:

mv	matrix-vector product
sv	solving a system of linear equations with matrix-vector operations
r	rank-1 update of a matrix
r2	rank-2 update of a matrix.

The PBLAS level 3 names can have the following additional characters in the `<mod>` field:

mm	matrix-matrix product
sm	solving a system of linear equations with matrix-matrix operations
rk	rank- k update of a matrix
r2k	rank- $2k$ update of a matrix.

The examples below show how to interpret PBLAS routine names:

pddot	<code><p> <d> <dot></code> : double-precision real distributed vector-vector dot product
pcdotc	<code><p> <c> <dot> <c></code> : complex distributed vector-vector dot product, conjugated
pscasum	<code><p> <sc> <asum></code> : sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
pcdotu	<code><p> <c> <dot> <u></code> : distributed vector-vector dot product, unconjugated, complex
psgemv	<code><p> <s> <ge> <mv></code> : distributed matrix-vector product, general matrix, single precision
pztrmm	<code><p> <z> <tr> <mm></code> : distributed matrix-matrix product, triangular matrix, double-precision complex.

PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions that perform distributed vector-vector operations. [Table "PBLAS Level 1 Routine Groups and Their Data Types"](#) lists the PBLAS Level 1 routine groups and the data types associated with them.

PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
p?amax	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
p?asum	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
p?axpy	s, d, c, z	Calculates distributed vector-scalar product
p?copy	s, d, c, z	Copies a distributed vector
p?dot	s, d	Calculates a dot product of two distributed real vectors
p?dotc	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated

Routine or Function Group	Data Types	Description
p?dotu	c, z	Calculates a dot product of two distributed complex vectors
p?nrm2	s, d, sc, dz	Calculates the 2-norm (Euclidean norm) of a distributed vector
p?scal	s, d, c, z, cs, zd	Calculates a product of a distributed vector by a scalar
p?swap	s, d, c, z	Swaps two distributed vectors

pamax

Computes the global index of the element of a distributed vector with maximum absolute value.

Syntax

```
call psamax(n, amax, indx, x, ix, jx, descx, incx)
call pdamax(n, amax, indx, x, ix, jx, descx, incx)
call pcamax(n, amax, indx, x, ix, jx, descx, incx)
call pzamax(n, amax, indx, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The functions pamax compute global index of the maximum element in absolute value of a distributed vector sub(x),

where sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vector sub(x), $n \geq 0$.
<i>x</i>	(local) REAL for psamax DOUBLE PRECISION for pdamax COMPLEX for pcamax DOUBLE COMPLEX for pzamax Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector sub(x).
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix sub(<i>x</i>), respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of sub(x). Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

<i>amax</i>	(global) REAL for psamax.
-------------	---------------------------

DOUBLE PRECISION for pdamax.
 COMPLEX for pcamax.
 DOUBLE COMPLEX for pzamax.
 Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.

indx (global) INTEGER. The global index of the maximum element in absolute value of the distributed vector $\text{sub}(x)$ only in its scope.

p?asum

Computes the sum of magnitudes of elements of a distributed vector.

Syntax

```
call psasum(n, asum, x, ix, jx, descx, incx)
call pscasum(n, asum, x, ix, jx, descx, incx)
call pdasum(n, asum, x, ix, jx, descx, incx)
call pdzasum(n, asum, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The functions p?asum compute the sum of the magnitudes of elements of a distributed vector $\text{sub}(x)$, where $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

n (global) INTEGER. The length of distributed vector $\text{sub}(x)$, $n \geq 0$.
x (local) REAL for psasum
 DOUBLE PRECISION for pdasum
 COMPLEX for pscasum
 DOUBLE COMPLEX for pdzasum
 Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$.
 This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx (global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
descx (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
incx (global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

asum (local) REAL for psasum and pscasum.
 DOUBLE PRECISION for pdasum and pdzasum
 Contains the sum of magnitudes of elements of the distributed vector only in its scope.

p?axpy

Computes a distributed vector-scalar product and adds the result to a distributed vector.

Syntax

```
call psaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?axpy routines perform the following operation with distributed vectors:

```
sub(y) := sub(y) + a*sub(x)
```

where:

a is a scalar;

sub(x) and *sub(y)* are *n*-element distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>a</i>	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Specifies the scalar <i>a</i> .
<i>x</i>	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy DOUBLE COMPLEX for pzaxpy Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psaxpy DOUBLE PRECISION for pdaxpy COMPLEX for pcaxpy

	DOUBLE COMPLEX for pzaxpy Array, DIMENSION ($jy-1)*m_y + iy+(n-1)*abs(incy)$). This array contains the entries of the distributed vector sub(y).
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix sub(Y), respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y.
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of sub(y). Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>Y</i>	Overwritten by $\text{sub}(y) := \text{sub}(y) + a * \text{sub}(x)$.
----------	---

p?copy

Copies one distributed vector to another vector.

Syntax

```
call pscopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pccopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call picopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?copy routines perform a copy operation with distributed vectors defined as

```
sub(y) = sub(x),
```

where sub(x) and sub(y) are *n*-element distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy INTEGER for picopy Array, DIMENSION ($jx-1)*m_x + ix+(n-1)*abs(incx)$). This array contains the entries of the distributed vector sub(x).

<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for <i>pscopy</i> DOUBLE PRECISION for <i>pdcopy</i> COMPLEX for <i>pccopy</i> DOUBLE COMPLEX for <i>pzccopy</i> INTEGER for <i>picopy</i> Array, DIMENSION $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten with the distributed vector $\text{sub}(x)$.
----------	---

p?dot

Computes the dot product of two distributed real vectors.

Syntax

```
call psdot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pddot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

```
dot = sub(x)' * sub(y)
```

where $\text{sub}(x)$ and $\text{sub}(y)$ are *n*-element distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$;
 $\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy=1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) REAL for <i>psdot</i>

	DOUBLE PRECISION for pddot Array, DIMENSION ($jx-1)*m_x + ix+(n-1)*abs(incx)$). This array contains the entries of the distributed vector sub(x).
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix sub(X), respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of sub(X). Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psdot DOUBLE PRECISION for pddot Array, DIMENSION ($jy-1)*m_y + iy+(n-1)*abs(incy)$). This array contains the entries of the distributed vector sub(y).
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix sub(Y), respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of sub(Y). Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>dot</i>	(local) REAL for psdot DOUBLE PRECISION for pddot Dot product of sub(x) and sub(y) only in their scope.
------------	---

p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

Syntax

```
call pcdotc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?dotu functions compute the dot product *dotc* of two distributed vectors one of them is conjugated:

```
dotc = conjg(sub(x)')*sub(y)
```

where sub(x) and sub(y) are n -element distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;
sub(y) denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Array, DIMENSION $(jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>dotc</i>	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Dot product of $\text{sub}(x)$ and $\text{sub}(y)$ only in their scope.
-------------	--

p?dotu

Computes the dot product of two distributed complex vectors.

Syntax

```
call pcdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?dotu functions compute the dot product *dotu* of two distributed vectors defined as

```
dotu =  $\text{sub}(x)' * \text{sub}(y)$ 
```

where $\text{sub}(x)$ and $\text{sub}(y)$ are *n*-element distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx=1$;

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy=1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
<code>x</code>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.
<code>y</code>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION $(jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>y</code> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<code>descy</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>y</code> .
<code>incy</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . <code>incy</code> must not be zero.

Output Parameters

<code>dotu</code>	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Dot product of <code>sub(x)</code> and <code>sub(y)</code> only in their scope.
-------------------	--

p?nrm2

Computes the Euclidean norm of a distributed vector.

Syntax

```
call psnrm2(n, norm2, x, ix, jx, descx, incx)
call pdnrm2(n, norm2, x, ix, jx, descx, incx)
call pscnrm2(n, norm2, x, ix, jx, descx, incx)
call pdznrm2(n, norm2, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The `p?nrm2` functions compute the Euclidean norm of a distributed vector `sub(x)`, where `sub(x)` is an n -element distributed vector.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
<code>x</code>	(local) REAL for <code>psnrm2</code> DOUBLE PRECISION for <code>pdnrm2</code> COMPLEX for <code>pscnnrm2</code> DOUBLE COMPLEX for <code>pdznrm2</code> Array, DIMENSION $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

Output Parameters

<code>norm2</code>	(local) REAL for <code>psnrm2</code> and <code>pscnnrm2</code> . DOUBLE PRECISION for <code>pdnrm2</code> and <code>pdznrm2</code> Contains the Euclidean norm of a distributed vector only in its scope.
--------------------	---

p?scal

Computes a product of a distributed vector by a scalar.

Syntax

```
call psscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pzscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?scal` routines multiplies a n -element distributed vector `sub(x)` by the scalar `a`:

```
sub(x) = a*sub(x),
```

where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

<code>n</code>	(global) INTEGER. The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
----------------	---

<i>a</i>	(global) REAL for psscal and pcscal DOUBLE PRECISION for pdscal and pdscal COMPLEX for pcscal DOUBLE COMPLEX for pzscal Specifies the scalar <i>a</i> .
<i>x</i>	(local) REAL for psscal DOUBLE PRECISION for pdscal COMPLEX for pcscal and pcscal DOUBLE COMPLEX for pzscal and pdscal Array, DIMENSION ($jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by the updated distributed vector $\text{sub}(x)$
----------	---

p?swap

Swaps two distributed vectors.

Syntax

```
call psswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

Given two distributed vectors $\text{sub}(x)$ and $\text{sub}(y)$, the p?swap routines return vectors $\text{sub}(y)$ and $\text{sub}(x)$ swapped, each replacing the other.

Here $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;
 $\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<i>n</i>	(global) INTEGER. The length of distributed vectors, $n\geq 0$.
<i>x</i>	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap

	Array, DIMENSION ($jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
$descx$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix x .
$incx$	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
y	(local) REAL for pswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, DIMENSION ($jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
iy, jy	(global) INTEGER. The row and column indices in the distributed matrix y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
$descy$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix y .
$incy$	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

x	Overwritten by distributed vector $\text{sub}(y)$.
y	Overwritten by distributed vector $\text{sub}(x)$.

PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. [Table "PBLAS Level 2 Routine Groups and Their Data Types"](#) lists the PBLAS Level 2 routine groups and the data types associated with them.

PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
p?gemv	s, d, c, z	Matrix-vector product using a distributed general matrix
p?agemv	s, d, c, z	Matrix-vector product using absolute values for a distributed general matrix
p?ger	s, d	Rank-1 update of a distributed general matrix
p?gerc	c, z	Rank-1 update (conjugated) of a distributed general matrix
p?geru	c, z	Rank-1 update (unconjugated) of a distributed general matrix
p?hemv	c, z	Matrix-vector product using a distributed Hermitian matrix
p?ahemv	c, z	Matrix-vector product using absolute values for a distributed Hermitian matrix

Routine Groups	Data Types	Description
p?her	c, z	Rank-1 update of a distributed Hermitian matrix
p?her2	c, z	Rank-2 update of a distributed Hermitian matrix
p?symv	s, d	Matrix-vector product using a distributed symmetric matrix
p?asymv	s, d	Matrix-vector product using absolute values for a distributed symmetric matrix
p?syr	s, d	Rank-1 update of a distributed symmetric matrix
p?syr2	s, d	Rank-2 update of a distributed symmetric matrix
p?trmv	s, d, c, z	Distributed matrix-vector product using a triangular matrix
p?atrmv	s, d, c, z	Distributed matrix-vector product using absolute values for a triangular matrix
p?trsv	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

p?gemv

Computes a distributed matrix-vector product using a general matrix.

Syntax

```
call psgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)

call pdgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)

call pcgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)

call pzgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?gemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*conjg(sub(A)')*sub(x) + beta*sub(y),
```

where

alpha and beta are scalars,

sub(A) is a m-by-n submatrix, sub(A) = A(ia:ia+m-1, ja:ja+n-1),

`sub(x)` and `sub(y)` are subvectors.

When `trans = 'N'` or `'n'`, `sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx = m_x`, and $X(ix: ix+n-1, jx)$ if `incx = 1`, `sub(y)` denotes $Y(iy, jy:jy+m-1)$ if `incy = m_y`, and $Y(iy: iy+m-1, jy)$ if `incy = 1`.

When `trans = 'T'` or `'t'`, or `'C'`, or `'c'`, `sub(x)` denotes $X(ix, jx:jx+m-1)$ if `incx = m_x`, and $X(ix: ix+m-1, jx)$ if `incx = 1`, `sub(y)` denotes $Y(iy, jy:jy+n-1)$ if `incy = m_y`, and $Y(iy: iy+m-1, jy)$ if `incy = 1`.

Input Parameters

<code>trans</code>	(global) CHARACTER*1. Specifies the operation: if <code>trans= 'N'</code> or <code>'n'</code> , then <code>sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y);</code> if <code>trans= 'T'</code> or <code>'t'</code> , then <code>sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y);</code> if <code>trans= 'C'</code> or <code>'c'</code> , then <code>sub(y) := alpha*conjg(subA')'*sub(x) + beta*sub(y).</code>
<code>m</code>	(global) INTEGER. Specifies the number of rows of the distributed matrix <code>sub(A)</code> , $m \geq 0$.
<code>n</code>	(global) INTEGER. Specifies the number of columns of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
<code>alpha</code>	(global) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, DIMENSION (<code>lld_a, LOCq(ja+n-1)</code>). Before entry this array must contain the local pieces of the distributed matrix <code>sub(A)</code> .
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>x</code>	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, DIMENSION ($jx-1)*m_x + ix+(n-1)*abs(incx)$) when <code>trans = 'N'</code> or <code>'n'</code> , and $(jx-1)*m_x + ix+(m-1)*abs(incx)$) otherwise. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.

<i>beta</i>	(global) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>sub(y)</i> need not be set on input.
<i>y</i>	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, DIMENSION (<i>jy</i> -1)* <i>m_y</i> + <i>i_y</i> +(<i>m</i> -1)*abs(<i>incy</i>) when <i>trans</i> = 'N' or 'n', and (<i>jy</i> -1)* <i>m_y</i> + <i>i_y</i> +(<i>n</i> -1)*abs(<i>incy</i>) otherwise. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>i_y, j_y</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <i>sub(y)</i> .
----------	---

p?agemv

Computes a distributed matrix-vector product using absolute values for a general matrix.

Syntax

```
call psagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)

call pdagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)

call pcagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)

call pzagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y,
            iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?agemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(conjg(sub(A')))*abs(sub(x)) + abs(beta*sub(y)),
```

where

alpha and *beta* are scalars,

sub(A) is a *m*-by-*n* submatrix, *sub(A)* = *A*(*ia*:*ia+m-1*, *ja*:*ja+n-1*),

sub(x) and *sub(y)* are subvectors.

When *trans* = 'N' or 'n',

sub(x) denotes $X(ix:ix, jx:jx+n-1)$ if *incx* = *m_x*, and

$X(ix:ix+n-1, jx:jx)$ if *incx* = 1,

sub(y) denotes $Y(iy:iy, jy:jy+m-1)$ if *incy* = *m_y*, and

$Y(iy:iy+m-1, jy:jy)$ if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c',

sub(x) denotes $X(ix:ix, jx:jx+m-1)$ if *incx* = *m_x*, and

$X(ix:ix+m-1, jx:jx)$ if *incx* = 1,

sub(y) denotes $Y(iy:iy, jy:jy+n-1)$ if *incy* = *m_y*, and

$Y(iy:iy+m-1, jy:jy)$ if *incy* = 1.

Input Parameters

trans

(global) CHARACTER*1. Specifies the operation:

```
if trans= 'N' or 'n', then sub(y) := |alpha| * |sub(A)| * |sub(x)| +
|beta*sub(y)|
if trans= 'T' or 't', then sub(y) := |alpha| * |sub(A)'| * |sub(x)| +
|beta*sub(y)|
if trans= 'C' or 'c', then sub(y) := |alpha| * |sub(A)'| * |sub(x)| +
|beta*sub(y)|.
```

m

(global) INTEGER. Specifies the number of rows of the distributed matrix
sub(A), $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix
sub(A), $n \geq 0$.

alpha

(global) REAL for psagemv
DOUBLE PRECISION for pdagemv
COMPLEX for pcagemv
DOUBLE COMPLEX for pzagemv
Specifies the scalar *alpha*.

a

(local) REAL for psagemv
DOUBLE PRECISION for pdagemv
COMPLEX for pcagemv
DOUBLE COMPLEX for pzagemv
Array, DIMENSION (*lld_a*, LOC_Q(*ja+n-1*)). Before entry this array must contain the local pieces of the distributed matrix *sub(A)*.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

<i>descA</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Array, DIMENSION (<i>jx</i> -1)* <i>m_x</i> + <i>ix</i> +(<i>n</i> -1)*abs(<i>incx</i>) when <i>trans</i> = 'N' or 'n', and (<i>jx</i> -1)* <i>m_x</i> + <i>ix</i> +(<i>m</i> -1)*abs(<i>incx</i>) otherwise. This array contains the entries of the distributed vector sub(<i>x</i>).
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix sub(<i>x</i>), respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of sub(<i>x</i>). Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>beta</i>	(global) REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then sub(<i>y</i>) need not be set on input.
<i>y</i>	(local) REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Array, DIMENSION (<i>jy</i> -1)* <i>m_y</i> + <i>iy</i> +(<i>m</i> -1)*abs(<i>incy</i>) when <i>trans</i> = 'N' or 'n', and (<i>jy</i> -1)* <i>m_y</i> + <i>iy</i> +(<i>n</i> -1)*abs(<i>incy</i>) otherwise. This array contains the entries of the distributed vector sub(<i>y</i>).
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix sub(<i>y</i>), respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of sub(<i>y</i>). Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector sub(<i>y</i>).
----------	--

p?ger

Performs a rank-1 update of a distributed general matrix.

Syntax

```
call psger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, descA)
call pdger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, descA)
```

Include Files

- C: mkl_pblas.h

Description

The p?ger routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,

sub(A) is a m -by- n distributed general matrix, $\text{sub}(A)=A(i_a:i_a+m-1, j_a:j_a+n-1)$,

sub(x) is an m -element distributed vector, *sub(y)* is an n -element distributed vector,

sub(x) denotes $X(ix, jx:jx+m-1)$ if $\text{incx} = m_x$, and $X(ix: ix+m-1, jx)$ if $\text{incx} = 1$,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $\text{incy} = m_y$, and $Y(iy: iy+n-1, jy)$ if $\text{incy} = 1$.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub(A)</i> , $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) REAL for psger DOUBLE REAL for pdger Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) REAL for psger DOUBLE REAL for pdger Array, DIMENSION at least $(j_x-1)*m_x + i_x + (m-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for psger DOUBLE REAL for pdger Array, DIMENSION at least $(j_y-1)*m_y + i_y + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) REAL for psger DOUBLE REAL for pdger Array, DIMENSION (<i>lld_a, LOCq(ja+n-1)</i>).

	Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix $\text{sub}(A)$.
----------	---

p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

Syntax

```
call pcgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja,
descra)
call pzgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja,
descra)
```

Include Files

- C: mkl_pblas.h

Description

The p?gerc routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(y)) + sub(A),
```

where:

alpha is a scalar,

sub(A) is a m -by- n distributed general matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$,

sub(x) is an m -element distributed vector, *sub(y)* is an n -element distributed vector,

sub(x) denotes $X(ix, jx:jx+m-1)$ if $\text{incx} = \text{m_x}$, and $X(ix: ix+m-1, jx)$ if $\text{incx} = 1$,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $\text{incy} = \text{m_y}$, and $Y(iy: iy+n-1, jy)$ if $\text{incy} = 1$.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least $(jx-1)*\text{m_x} + ix + (n-1)*\text{abs}(\text{incx})$.

	This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>x</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>x</code> .
<code>incx</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.
<code>y</code>	(local) COMPLEX for <code>pcgerc</code> DOUBLE COMPLEX for <code>pzgerc</code> Array, DIMENSION at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>y</code> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<code>descy</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>y</code> .
<code>incy</code>	(global) INTEGER. Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and <code>m_y</code> . <code>incy</code> must not be zero.
<code>a</code>	(local) COMPLEX for <code>pcgerc</code> DOUBLE COMPLEX for <code>pzgerc</code> Array, DIMENSION at least $(lld_a, \text{LOCq}(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .

Output Parameters

<code>a</code>	Overwritten by the updated distributed matrix <code>sub(A)</code> .
----------------	---

p?geru

Performs a rank-1 update (unconjugated) of a distributed general matrix.

Syntax

```
call pcgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja,
desca)

call pzgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja,
desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?geru routines perform a matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,
sub(A) is a m -by- n distributed general matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$,
sub(x) is an m -element distributed vector, $\text{sub}(y)$ is an n -element distributed vector,
sub(x) denotes $X(ix, jx:jx+m-1)$ if $\text{incx} = m_x$, and $X(ix: ix+m-1, jx)$ if $\text{incx} = 1$,
sub(y) denotes $Y(iy, jy:jy+n-1)$ if $\text{incy} = m_y$, and $Y(iy: iy+n-1, jy)$ if $\text{incy} = 1$.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Array, DIMENSION at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for <code>pcgeru</code> DOUBLE COMPLEX for <code>pzgeru</code> Array, DIMENSION at least $(lld_a, \text{LOC}_q(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

`a`

Overwritten by the updated distributed matrix $\text{sub}(A)$.

p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

Syntax

```
call pchemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
           jy, descy, incy)
call pzhemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
           jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?hemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

where:

`alpha` and `beta` are scalars,

`sub(A)` is a n -by- n Hermitian distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$,

`sub(x)` and `sub(y)` are distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = \text{m_x}$, and $X(ix: ix+n-1, jx)$ if $\text{incx} = 1$,

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $\text{incy} = \text{m_y}$, and $Y(iy: iy+n-1, jy)$ if $\text{incy} = 1$.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(A)$ is used: If <code>uplo</code> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used. If <code>uplo</code> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.
<code>n</code>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<code>alpha</code>	(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION (<code>lld_a, LOCq(ja+n-1)</code>). This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry when <code>uplo</code> = 'U' or 'u', the n -by- n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when <code>uplo</code> = 'L' or 'l', the n -by- n lower

triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>x</i>	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector $\text{sub}(y)$.
----------	---

p?ahemv

Computes a distributed matrix-vector product using absolute values for a Hermitian matrix.

Syntax

```
call pcahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pzahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?ahemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* Hermitian distributed matrix, *sub(A)=A(ia:ia+n-1, ja:ja+n-1)*,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if *incx* = *m_x*, and $X(ix: ix+n-1, jx)$ if *incx* = 1,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if *incy* = *m_y*, and $Y(iy: iy+n-1, jy)$ if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+n-1</i>)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry when <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.

<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>beta</i>	(global) COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>sub(y)</i> need not be set on input.
<i>y</i>	(local) COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Array, DIMENSION at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <i>sub(y)</i> .
----------	---

p?her

Performs a rank-1 update of a distributed Hermitian matrix.

Syntax

```
call pcher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pzher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Include Files

- C:\mkl_pblas.h

Description

The p?her routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(x)') + sub(A),
```

where:

alpha is a real scalar,

sub(A) is a *n*-by-*n* distributed Hermitian matrix, *sub(A)=A(ia:ia+n-1, ja:ja+n-1)*,

sub(x) is distributed vector.

sub(x) denotes *X(ix, jx:jx+n-1)* if *incx = m_x*, and *X(ix: ix+n-1, jx)* if *incx = 1*.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used:
-------------	---

	If $uplo = 'U'$ or ' u ', then the upper triangular part of the $\text{sub}(A)$ is used. If $uplo = 'L'$ or ' l ', then the low triangular part of the $\text{sub}(A)$ is used.
n	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
α	(global) REAL for pcher DOUBLE REAL for pzher Specifies the scalar α .
x	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
desc_x	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix x .
$incx$	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
a	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher Array, DIMENSION ($lld_a, \text{LOC}_q(ja+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry with $uplo = 'U'$ or ' u ', the n -by- n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with $uplo = 'L'$ or ' l ', the n -by- n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
ia, ja	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
desc_a	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

a	With $uplo = 'U'$ or ' u ', the upper triangular part of the array a is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$. With $uplo = 'L'$ or ' l ', the lower triangular part of the array a is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.
-----	--

p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

Syntax

```
call pcher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
```

```
call pzher2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?her2 routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conj(sub(y)') + conj(alpha)*sub(y)*conj(sub(x)'), + sub(A),
```

where:

alpha is a scalar,

sub(A) is a n -by- n distributed Hermitian matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = m_x$, and $X(ix: ix+n-1, jx)$ if $\text{incx} = 1$,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $\text{incy} = m_y$, and $Y(iy: iy+n-1, jy)$ if $\text{incy} = 1$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed Hermitian matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(\text{incx})$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Array, DIMENSION at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(\text{incy})$. This array contains the entries of the distributed vector <i>sub(y)</i> .

<i>i_y, j_y</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(Y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.
<i>a</i>	(local) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Array, DIMENSION (<i>lld_a</i> , LOCQ(<i>ja+n-1</i>)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry with <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and with <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix <i>sub(A)</i> . With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated distributed matrix <i>sub(A)</i> .
----------	--

p?symv

Computes a distributed matrix-vector product using a symmetric matrix.

Syntax

```
call pssymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pdsymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- C:\mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

where:

alpha and *beta* are scalars,

sub(A) is a n -by- n symmetric distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix: ix+n-1, jx)$ if $incx = 1$,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix *sub(A)* is used:
If *uplo* = 'U' or 'u', then the upper triangular part of the *sub(A)* is used.
If *uplo* = 'L' or 'l', then the low triangular part of the *sub(A)* is used.

n

(global) INTEGER. Specifies the order of the distributed matrix *sub(A)*, $n \geq 0$.

alpha

(global) REAL for pssymv
DOUBLE REAL for pdssymv
Specifies the scalar *alpha*.

a

(local) REAL for pssymv
DOUBLE REAL for pdssymv
Array, DIMENSION (*lld_a*, LOCQ(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix *sub(A)*.
Before entry when *uplo* = 'U' or 'u', the n -by- n upper triangular part of the distributed matrix *sub(A)* must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of *sub(A)* is not referenced, and when *uplo* = 'L' or 'l', the n -by- n lower triangular part of the distributed matrix *sub(A)* must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of *sub(A)* is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

x

(local) REAL for pssymv
DOUBLE REAL for pdssymv
Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector *sub(x)*.

ix, jx

(global) INTEGER. The row and column indices in the distributed matrix *x* indicating the first row and the first column of the submatrix *sub(x)*, respectively.

descx

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *x*.

incx

(global) INTEGER. Specifies the increment for the elements of *sub(x)*. Only two values are supported, namely 1 and m_x . *incx* must not be zero.

beta

(global) REAL for pssymv
DOUBLE REAL for pdssymv
Specifies the scalar *beta*. When *beta* is set to zero, then *sub(y)* need not be set on input.

<i>y</i>	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, DIMENSION at least $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector $\text{sub}(y)$.
----------	---

p?asymv

Computes a distributed matrix-vector product using absolute values for a symmetric matrix.

Syntax

```
call psasymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
jy, descy, incy)

call pdasymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy,
jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* symmetric distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes $X(ix, jx:jx+n-1)$ if *incx* = m_x , and $X(ix: ix+n-1, jx)$ if *incx* = 1,

sub(y) denotes $Y(iy, jy:jy+n-1)$ if *incy* = m_y , and $Y(iy: iy+n-1, jy)$ if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.

<i>alpha</i>	(global) REAL for psasymv DOUBLE REAL for pdasymv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for psasymv DOUBLE PRECISION for pdasymv Array, DIMENSION (<i>l1d_a</i> , LOCQ(<i>ja</i> + <i>n</i> -1)). This array contains the local pieces of the distributed matrix sub(A). Before entry when <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix sub(A) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(A) is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>n</i> -by- <i>n</i> lower triangular part of the distributed matrix sub(A) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(A) is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix sub(A), respectively.
<i>desc_a</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A.
<i>x</i>	(local) REAL for psasymv DOUBLE PRECISION for pdasymv Array, DIMENSION at least (<i>jx</i> -1)* <i>m_x</i> + <i>ix</i> +(<i>n</i> -1)*abs(<i>incx</i>). This array contains the entries of the distributed vector sub(x).
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix sub(x), respectively.
<i>desc_x</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X.
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of sub(x). Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>beta</i>	(global) REAL for psasymv DOUBLE PRECISION for pdasymv Specifies the scalar beta. When beta is set to zero, then sub(y) need not be set on input.
<i>y</i>	(local) REAL for psasymv DOUBLE PRECISION for pdasymv Array, DIMENSION at least (<i>jy</i> -1)* <i>m_y</i> + <i>iy</i> +(<i>n</i> -1)*abs(<i>incy</i>). This array contains the entries of the distributed vector sub(y).
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix sub(y), respectively.
<i>desc_y</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix Y.
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of sub(y). Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

y Overwritten by the updated distributed vector sub(y).

p?syr

Performs a rank-1 update of a distributed symmetric matrix.

Syntax

```
call pssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pdssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?syr routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(x)' + sub(A),
```

where:

alpha is a scalar,

sub(A) is a n -by- n distributed symmetric matrix, $\text{sub}(A)=A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$,

sub(x) is distributed vector.

sub(x) denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = m_x$, and $X(ix: ix+n-1, jx)$ if $\text{incx} = 1$,

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) REAL for pssyr DOUBLE REAL for pdssyr Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) REAL for pssyr DOUBLE REAL for pdssyr Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(\text{incx})$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>a</i>	(local) REAL for pssyr DOUBLE REAL for pdssyr Array, DIMENSION (<i>lld_a</i> , LOC _q (<i>ja</i> + <i>n</i> -1)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> .

Before entry with $uplo = 'U'$ or ' u ', the n -by- n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with $uplo = 'L'$ or ' l ', the n -by- n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

$desca$

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

a

With $uplo = 'U'$ or ' u ', the upper triangular part of the array a is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$.

With $uplo = 'L'$ or ' l ', the lower triangular part of the array a is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.

p?syr2

Performs a rank-2 update of a distributed symmetric matrix.

Syntax

```
call pssyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
call pdssyr2(uplo, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia,
ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?syr2 routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + alpha*sub(y)*sub(x)' + sub(A),
```

where:

α is a scalar,

$\text{sub}(A)$ is a n -by- n distributed symmetric matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ and $\text{sub}(y)$ are distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix: ix+n-1, jx)$ if $incx = 1$,

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed symmetric matrix $\text{sub}(A)$ is used: If $\text{uplo} = 'U'$ or ' <u>u</u> ', then the upper triangular part of the $\text{sub}(A)$ is used. If $\text{uplo} = 'L'$ or ' <l>', then the low triangular part of the $\text{sub}(A)$ is used.</l>
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) REAL for pssyr2 DOUBLE REAL for pdssyr2 Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) REAL for pssyr2 DOUBLE REAL for pdssyr2 Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>x</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>x</i> .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>y</i>	(local) REAL for pssyr2 DOUBLE REAL for pdssyr2 Array, DIMENSION at least $(jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>y</i> .
<i>incy</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.
<i>a</i>	(local) REAL for pssyr2 DOUBLE REAL for pdssyr2 Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+n-1</i>)). This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry with $\text{uplo} = 'U'$ or ' <u>u</u> ', the n -by- n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with $\text{uplo} = 'L'$ or ' <l>', the n-by-n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.</l>
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

a

With $uplo = 'U'$ or 'u', the upper triangular part of the array a is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$.

With $uplo = 'L'$ or '', the lower triangular part of the array a is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.

p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

Syntax

```
call pstrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The p?trmv routines perform one of the following distributed matrix-vector operations defined as

$\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$, or $\text{sub}(x) := \text{sub}(A)' * \text{sub}(x)$, or $\text{sub}(x) := \text{conjg}(\text{sub}(A)') * \text{sub}(x)$,

where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix: ix+n-1, jx)$ if $incx = 1$,

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular:
 if $uplo = 'U'$ or 'u', then the matrix is upper triangular;
 if $uplo = 'L'$ or '', then the matrix is low triangular.

trans

(global) CHARACTER*1. Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation:
 if $transa = 'N'$ or '', then $\text{sub}(x) := \text{sub}(A) * \text{sub}(x)$;
 if $transa = 'T'$ or '', then $\text{sub}(x) := \text{sub}(A)' * \text{sub}(x)$;
 if $transa = 'C'$ or '', then $\text{sub}(x) := \text{conjg}(\text{sub}(A)') * \text{sub}(x)$.

diag

(global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular:
 if $diag = 'U'$ or 'u' then the matrix is unit triangular;
 if $diag = 'N'$ or '', then the matrix is not unit triangular.

<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>a</i>	(local) REAL for <code>pstrmv</code> DOUBLE PRECISION for <code>pdtrmv</code> COMPLEX for <code>pctrmv</code> DOUBLE COMPLEX for <code>pztrmv</code> Array, DIMENSION at least $(\text{lld}_a, \text{LOCq}(1, ja+n-1))$. Before entry with $\text{uplo} = 'U'$ or ' u ', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with $\text{uplo} = 'L'$ or ' l ', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced . When $\text{diag} = 'U'$ or ' u ', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desc<i>a</i></i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>x</i>	(local) REAL for <code>pstrmv</code> DOUBLE PRECISION for <code>pdtrmv</code> COMPLEX for <code>pctrmv</code> DOUBLE COMPLEX for <code>pztrmv</code> Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>desc<i>x</i></i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix X .
<i>inc<i>x</i></i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by the transformed distributed vector $\text{sub}(x)$.
----------	---

p?atrmv

Computes a distributed matrix-vector product using absolute values for a triangular matrix.

Syntax

```
call psatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pdatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

```
call pcatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)

call pzatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx,
beta, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?atrmv routines perform one of the following distributed matrix-vector operations defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)), or
sub(y) := abs(alpha)*abs(sub(A'))*abs(sub(x)) + abs(beta*sub(y)), or
sub(y) := abs(alpha)*abs(conjg(sub(A')))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, *sub(A)* = *A*(*ia*:*ia+n-1*, *ja*:*ja+n-1*),

sub(x) is an *n*-element distributed vector.

sub(x) denotes *X*(*ix*, *jx*:*jx+n-1*) if *incx* = *m_x*, and *X*(*ix*: *ix+n-1*, *jx*) if *incx* = 1.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix <i>sub(A)</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) CHARACTER*1. Specifies the form of <i>op</i> (<i>sub(A)</i>) used in the matrix equation: if <i>trans</i> = 'N' or 'n', then <i>sub(y)</i> := <i>alpha</i> * <i>sub(A)</i> * <i>sub(x)</i> + <i>beta</i> * <i>sub(y)</i> ; if <i>trans</i> = 'T' or 't', then <i>sub(y)</i> := <i>alpha</i> * <i>sub(A)</i> ' * <i>sub(x)</i> + <i>beta</i> * <i>sub(y)</i> ; if <i>trans</i> = 'C' or 'c', then <i>sub(y)</i> := <i>alpha</i> * <i>conjg</i> (<i>sub(A)</i> ') * <i>sub(x)</i> + <i>beta</i> * <i>sub(y)</i> .
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix <i>sub(A)</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix <i>sub(A)</i> , <i>n</i> ≥0.
<i>alpha</i>	(global) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv

	DOUBLE COMPLEX for pzatrmv Array, DIMENSION at least (lld_a , $\text{LOCq}(1, ja+n-1)$). Before entry with $uplo = 'U'$ or ' u ', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with $uplo = 'L'$ or ' l ', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. When $diag = 'U'$ or ' u ', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.
ia, ja	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
$desc_a$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
x	(local) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Array, DIMENSION at least ($jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
$desc_x$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix x .
$incx$	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
$beta$	(global) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Specifies the scalar β . When β is set to zero, then $\text{sub}(y)$ need not be set on input.
y	(local) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Array, DIMENSION ($jy-1)*m_y + iy+(m-1)*\text{abs}(incy)$ when $trans = 'N'$ or ' n ', and ($jy-1)*m_y + iy+(n-1)*\text{abs}(incy)$ otherwise. This array contains the entries of the distributed vector $\text{sub}(y)$.
iy, jy	(global) INTEGER. The row and column indices in the distributed matrix y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
$desc_y$	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix y .

incy (global) INTEGER. Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . *incy* must not be zero.

Output Parameters

x Overwritten by the transformed distributed vector $\text{sub}(x)$.

p?trsv

Solves a system of linear equations whose coefficients are in a distributed triangular matrix.

Syntax

```
call pstrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The p?trsv routines solve one of the systems of equations:

$\text{sub}(A) * \text{sub}(x) = b$, or $\text{sub}(A)' * \text{sub}(x) = b$, or $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$,

where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

b and $\text{sub}(x)$ are n -element distributed vectors,

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $\text{incx} = m_x$, and $X(ix: ix+n-1, jx)$ if $\text{incx} = 1$.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular:
 if *uplo* = 'U' or 'u', then the matrix is upper triangular;
 if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans (global) CHARACTER*1. Specifies the form of the system of equations:
 if *transa* = 'N' or 'n', then $\text{sub}(A) * \text{sub}(x) = b$;
 if *transa* = 'T' or 't', then $\text{sub}(A)' * \text{sub}(x) = b$;
 if *transa* = 'C' or 'c', then $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$.

diag (global) CHARACTER*1. Specifies whether the matrix $\text{sub}(A)$ is unit triangular:
 if *diag* = 'U' or 'u' then the matrix is unit triangular;
 if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n (global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.

<i>a</i>	(local) REAL for <code>pstrsv</code> DOUBLE PRECISION for <code>pdtrsv</code> COMPLEX for <code>pctrsv</code> DOUBLE COMPLEX for <code>pztrsv</code> Array, DIMENSION at least $(\text{lld}_a, \text{LOCq}(1, ja+n-1))$. Before entry with $\text{uplo} = 'U'$ or ' u ', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with $\text{uplo} = 'L'$ or ' l ', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. When $\text{diag} = 'U'$ or ' u ', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>descA</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>x</i>	(local) REAL for <code>pstrsv</code> DOUBLE PRECISION for <code>pdtrsv</code> COMPLEX for <code>pctrsv</code> DOUBLE COMPLEX for <code>pztrsv</code> Array, DIMENSION at least $(jx-1)*m_x + ix+(n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$. Before entry, $\text{sub}(x)$ must contain the n -element right-hand side distributed vector b .
<i>ix, jx</i>	(global) INTEGER. The row and column indices in the distributed matrix x indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix x .
<i>incx</i>	(global) INTEGER. Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten with the solution vector.
----------	---------------------------------------

PBLAS Level 3 Routines

The PBLAS Level 3 routines perform distributed matrix-matrix operations. [Table "PBLAS Level 3 Routine Groups and Their Data Types"](#) lists the PBLAS Level 3 routine groups and the data types associated with them.

PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
<code>p?geadd</code>	s, d, c, z	Distributed matrix-matrix sum of general matrices

Routine Group	Data Types	Description
p?tradd	s, d, c, z	Distributed matrix-matrix sum of triangular matrices
p?gemm	s, d, c, z	Distributed matrix-matrix product of general matrices
p?hemm	c, z	Distributed matrix-matrix product, one matrix is Hermitian
p?herk	c, z	Rank-k update of a distributed Hermitian matrix
p?her2k	c, z	Rank-2k update of a distributed Hermitian matrix
p?simm	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
p?syrk	s, d, c, z	Rank-k update of a distributed symmetric matrix
p?syr2k	s, d, c, z	Rank-2k update of a distributed symmetric matrix
p?tran	s, d	Transposition of a real distributed matrix
p?tranc	c, z	Transposition of a complex distributed matrix (conjugated)
p?tranu	c, z	Transposition of a complex distributed matrix
p?trmm	s, d, c, z	Distributed matrix-matrix product, one matrix is triangular
p?trsm	s, d, c, z	Solution of a distributed matrix equation, one matrix is triangular

p?geadd

Performs sum operation for two distributed general matrices.

Syntax

```
call psgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pcgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C:\mkl_pblas.h

Description

The p?geadd routines perform sum operation for two distributed general matrices. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*op(sub(A)),
```

where:

op(x) is one of op(x) = x, or op(x) = x',

alpha and beta are scalars,

sub(C) is an m-by-n distributed matrix, sub(C)=C(ic:ic+m-1, jc:jc+n-1).

sub(A) is a distributed matrix, sub(A)=A(ia:ia+n-1, ja:ja+m-1).

Input Parameters

<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>op</i> (<i>sub</i> (<i>A</i>)) := <i>sub</i> (<i>A</i>); if <i>trans</i> = 'T' or 't', then <i>op</i> (<i>sub</i> (<i>A</i>)) := <i>sub</i> (<i>A</i>)'; if <i>trans</i> = 'C' or 'c', then <i>op</i> (<i>sub</i> (<i>A</i>)) := <i>sub</i> (<i>A</i>)'.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub</i> (<i>C</i>) and the number of columns of the submatrix <i>sub</i> (<i>A</i>), <i>m</i> ≥ 0.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub</i> (<i>C</i>) and the number of rows of the submatrix <i>sub</i> (<i>A</i>), <i>n</i> ≥ 0.
<i>alpha</i>	(global) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja</i> + <i>m</i> -1)). This array contains the local pieces of the distributed matrix <i>sub</i> (<i>A</i>).
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub</i> (<i>A</i>), respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>sub</i> (<i>C</i>) need not be set on input.
<i>c</i>	(local) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Array, DIMENSION (<i>lld_c</i> , LOCq(<i>jc</i> + <i>n</i> -1)). This array contains the local pieces of the distributed matrix <i>sub</i> (<i>C</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub</i> (<i>C</i>), respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?tradd

Performs sum operation for two distributed triangular matrices.

Syntax

```
call pstradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pdtradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pctradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
call pztradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, desc)
```

Include Files

- C:\mkl_pblas.h

Description

The p?tradd routines perform sum operation for two distributed triangular matrices. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*op(sub(A)),
```

where:

`op(x)` is one of `op(x) = x`, or `op(x) = x'`, or `op(x) = conjg(x')`.

`alpha` and `beta` are scalars,

`sub(C)` is an m -by- n distributed matrix, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+m-1)`.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Specifies whether the distributed matrix <code>sub(C)</code> is upper or lower triangular: if <code>uplo = 'U'</code> or <code>'u'</code> , then the matrix is upper triangular; if <code>uplo = 'L'</code> or <code>'l'</code> , then the matrix is low triangular.
<code>trans</code>	(global) CHARACTER*1. Specifies the operation: if <code>trans = 'N'</code> or <code>'n'</code> , then <code>op(sub(A)) := sub(A)</code> ; if <code>trans = 'T'</code> or <code>'t'</code> , then <code>op(sub(A)) := sub(A)'</code> ; if <code>trans = 'C'</code> or <code>'c'</code> , then <code>op(sub(A)) := conjg(sub(A)')</code> .
<code>m</code>	(global) INTEGER. Specifies the number of rows of the distributed matrix <code>sub(C)</code> and the number of columns of the submatrix <code>sub(A)</code> , $m \geq 0$.
<code>n</code>	(global) INTEGER. Specifies the number of columns of the distributed matrix <code>sub(C)</code> and the number of rows of the submatrix <code>sub(A)</code> , $n \geq 0$.
<code>alpha</code>	(global) REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd

	Array , DIMENSION (lld_a , LOCq($ja+m-1$)). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>beta</i>	(global) REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd Array , DIMENSION (lld_c , LOCq($jc+n-1$)). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.

Syntax

```
call psgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descC)

call pdgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descC)

call pcgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descC)

call pzgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta,
c, ic, jc, descC)
```

Include Files

- C:\mkl_pblas.h

Description

The p?gemm routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

```
sub(C) := alpha*op(sub(A))*op(sub(B)) + beta*sub(C),
```

where:

op(x) is one of *op(x) = x*, or *op(x) = x'*,

alpha and *beta* are scalars,

sub(A)=A(ia:ia+m-1, ja:ja+k-1), *sub(B)=B(ib:ib+k-1, jb:jb+n-1)*, and *sub(C)=C(ic:ic+m-1, jc:jc+n-1)*, are distributed matrices.

Input Parameters

<i>transa</i>	(global) CHARACTER*1. Specifies the form of <i>op(sub(A))</i> used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then <i>op(sub(A)) = sub(A)</i> ; if <i>transa</i> = 'T' or 't', then <i>op(sub(A)) = sub(A)'</i> ; if <i>transa</i> = 'C' or 'c', then <i>op(sub(A)) = sub(A)''</i> .
<i>transb</i>	(global) CHARACTER*1. Specifies the form of <i>op(sub(B))</i> used in the matrix multiplication: if <i>transb</i> = 'N' or 'n', then <i>op(sub(B)) = sub(B)</i> ; if <i>transb</i> = 'T' or 't', then <i>op(sub(B)) = sub(B)'</i> ; if <i>transb</i> = 'C' or 'c', then <i>op(sub(B)) = sub(B)''</i> .
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrices <i>op(sub(A))</i> and <i>sub(C)</i> , <i>m</i> ≥ 0.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrices <i>op(sub(B))</i> and <i>sub(C)</i> , <i>n</i> ≥ 0. The value of <i>n</i> must be at least zero.
<i>k</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>op(sub(A))</i> and the number of rows of the distributed matrix <i>op(sub(B))</i> . The value of <i>k</i> must be greater than or equal to 0.
<i>alpha</i>	(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar <i>alpha</i> . When <i>alpha</i> is equal to zero, then the local entries of the arrays <i>a</i> and <i>b</i> corresponding to the entries of the submatrices <i>sub(A)</i> and <i>sub(B)</i> respectively need not be set on input.
<i>a</i>	(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<i>lld_a, kla</i>), where <i>kla</i> is <i>LOCc(ja+k-1)</i> when <i>transa</i> = 'N' or 'n', and is <i>LOCq(ja+m-1)</i> otherwise. Before entry this array must contain the local pieces of the distributed matrix <i>sub(A)</i> .
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively

<i>descA</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<i>lld_b</i> , <i>k1b</i>), where <i>k1b</i> is LOCc(<i>jb+n-1</i>) when <i>transb</i> = 'N' or 'n', and is LOCq(<i>jb+k-1</i>) otherwise. Before entry this array must contain the local pieces of the distributed matrix sub(<i>B</i>).
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix sub(<i>B</i>), respectively
<i>descB</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then sub(<i>C</i>) need not be set on input.
<i>c</i>	(local) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (<i>lld_a</i> , LOCq(<i>jc+n-1</i>)). Before entry this array must contain the local pieces of the distributed matrix sub(<i>C</i>).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix sub(<i>C</i>), respectively
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> distributed matrix <i>alpha</i> *op(sub(<i>A</i>)) *op(sub(<i>B</i>)) + <i>beta</i> *sub(<i>C</i>).
----------	--

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

```
call pchemm(side, uplo, m, n, alpha, a, ia, ja, descA, b, ib, jb, descB, beta, c, ic, jc, descC)

call pzhemm(side, uplo, m, n, alpha, a, ia, ja, descA, b, ib, jb, descB, beta, c, ic, jc, descC)
```

Include Files

- C:\mkl_pblas.h

Description

The p?hemm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

```
sub(C) := alpha * sub(A) * sub(B) + beta * sub(C),
```

or

```
sub(C) := alpha * sub(B) * sub(A) + beta * sub(C),
```

where:

alpha and *beta* are scalars,

sub(A) is a Hermitian distributed matrix, *sub(A)* = $A(ia:ia+m-1, ja:ja+m-1)$, if *side* = 'L', and *sub(A)* = $A(ia:ia+n-1, ja:ja+n-1)$, if *side* = 'R'.

sub(B) and *sub(C)* are *m*-by-*n* distributed matrices.

sub(B) = $B(ib:ib+m-1, jb:jb+n-1)$, *sub(C)* = $C(ic:ic+m-1, jc:jc+n-1)$.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether the Hermitian distributed matrix <i>sub(A)</i> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(A)</i> * <i>sub(B)</i> + <i>beta</i> * <i>sub(C)</i> ; if <i>side</i> = 'R' or 'r', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(B)</i> * <i>sub(A)</i> + <i>beta</i> * <i>sub(C)</i> .
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distribute submatrix <i>sub(C)</i> , <i>m</i> ≥ 0.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distribute submatrix <i>sub(C)</i> , <i>n</i> ≥ 0.
<i>alpha</i>	(global) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (<i>lld_a</i> , LOCq(<i>ja+na-1</i>)). Before entry this array must contain the local pieces of the symmetric distributed matrix <i>sub(A)</i> , such that when <i>uplo</i> = 'U' or 'u', the <i>na</i> -by- <i>na</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub(A)</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the <i>na</i> -by- <i>na</i> lower triangular part of the distributed matrix <i>sub(A)</i> must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of <i>sub(A)</i> is not referenced.
<i>ia</i> , <i>ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for pchemm

	DOUBLE COMPLEX for pzhemm Array, DIMENSION (lld_b , LOCq($jb+n-1$)). Before entry this array must contain the local pieces of the distributed matrix sub(B).
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix sub(B), respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix B .
<i>beta</i>	(global) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then sub(C) need not be set on input.
<i>c</i>	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (lld_c , LOCq($jc+n-1$)). Before entry this array must contain the local pieces of the distributed matrix sub(C).
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix sub(C), respectively
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

<i>c</i>	Overwritten by the m -by- n updated distributed matrix.
----------	---

p?herk

Performs a rank- k update of a distributed Hermitian matrix.

Syntax

```
call pcherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pzherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

Include Files

- C: mkl_pblas.h

Description

The p?herk routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha * sub(A) * conjg(sub(A)') + beta * sub(C),
```

or

```
sub(C) := alpha * conjg(sub(A)) * sub(A) + beta * sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an n -by- n Hermitian distributed matrix, sub(C) = C ($ic:ic+n-1$, $jc:jc+n-1$).

sub(A) is a distributed matrix, sub(A) = A ($ia:ia+n-1$, $ja:ja+k-1$), if *trans* = 'N' or 'n', and sub(A) = A ($ia:ia+k-1$, $ja:ja+n-1$) otherwise.

Input Parameters

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(C)$ is used: If $\text{uplo} = \text{'U'}$ or 'u' , then the upper triangular part of the $\text{sub}(C)$ is used. If $\text{uplo} = \text{'L'}$ or 'l' , then the low triangular part of the $\text{sub}(C)$ is used.
<i>trans</i>	(global) CHARACTER*1. Specifies the operation: if $\text{trans} = \text{'N'}$ or 'n' , then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(A))$ + $\beta * \text{sub}(C)$; if $\text{trans} = \text{'C'}$ or 'c' , then $\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(A)$ + $\beta * \text{sub}(C)$.
<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>k</i>	(global) INTEGER. On entry with $\text{trans} = \text{'N'}$ or 'n' , <i>k</i> specifies the number of columns of the distributed matrix $\text{sub}(A)$, and on entry with $\text{trans} = \text{'T'}$ or 't' or 'C' or 'c' , <i>k</i> specifies the number of rows of the distributed matrix $\text{sub}(A)$, $k \geq 0$.
<i>alpha</i>	(global) REAL for pcherk DOUBLE PRECISION for pzherk Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for pcherk DOUBLE COMPLEX for pzherk Array, DIMENSION (<i>lld_a</i> , <i>kla</i>), where <i>kla</i> is $\text{LOCq}(ja+k-1)$ when $\text{trans} = \text{'N'}$ or 'n' , and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with $\text{trans} = \text{'N'}$ or 'n' , this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) REAL for pcherk DOUBLE PRECISION for pzherk Specifies the scalar <i>beta</i> .
<i>c</i>	(local) COMPLEX for pcherk DOUBLE COMPLEX for pzherk Array, DIMENSION (<i>lld_c</i> , $\text{LOCq}(jc+n-1)$). Before entry with $\text{uplo} = \text{'U'}$ or 'u' , this array contains n -by- n upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced. Before entry with $\text{uplo} = \text{'L'}$ or 'l' , this array contains n -by- n lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

c

With $\text{uplo} = \text{'U'}$ or 'u' , the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.
 With $\text{uplo} = \text{'L'}$ or 'l' , the lower triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

Syntax

Fortran 77:

```
call pcher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descC)
call pzher2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descC)
```

Include Files

- C: mkl_pblas.h

Description

The p?her2k routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)) + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)) + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)) * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

α and β are scalars,

$\text{sub}(C)$ is an n -by- n Hermitian distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$, if $\text{trans} = \text{'N'}$ or 'n' , and $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

$\text{sub}(B)$ is a distributed matrix, $\text{sub}(B) = B(ib:ib+n-1, jb:jb+k-1)$, if $\text{trans} = \text{'N'}$ or 'n' , and $\text{sub}(B) = B(ib:ib+k-1, jb:jb+n-1)$ otherwise.

Input Parameters

uplo

(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix $\text{sub}(C)$ is used:

If $\text{uplo} = \text{'U'}$ or 'u' , then the upper triangular part of the $\text{sub}(C)$ is used.

If $\text{uplo} = \text{'L'}$ or 'l' , then the low triangular part of the $\text{sub}(C)$ is used.

trans

(global) CHARACTER*1. Specifies the operation:

if $\text{trans} = \text{'N'}$ or 'n' , then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{conjg}(\text{sub}(B)) + \text{conjg}(\alpha) * \text{sub}(B) * \text{conjg}(\text{sub}(A)) + \beta * \text{sub}(C);$

if $\text{trans} = \text{'C'}$ or 'c' , then $\text{sub}(C) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(A) + \text{conjg}(\alpha) * \text{conjg}(\text{sub}(B)) * \text{sub}(A) + \beta * \text{sub}(C).$

<i>n</i>	(global) INTEGER. Specifies the order of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>k</i>	(global) INTEGER. On entry with $\text{trans} = 'N'$ or ' <i>n</i> ', <i>k</i> specifies the number of columns of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, and on entry with $\text{trans} = 'C'$ or ' <i>c</i> ' , <i>k</i> specifies the number of rows of the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$, $k \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Array, DIMENSION (<i>lld_a</i> , <i>kla</i>), where <i>kla</i> is $\text{LOCq}(ja+k-1)$ when $\text{trans} = 'N'$ or ' <i>n</i> ', and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or ' <i>n</i> ', this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Array, DIMENSION (<i>lld_b</i> , <i>klb</i>), where <i>klb</i> is $\text{LOCq}(jb+k-1)$ when $\text{trans} = 'N'$ or ' <i>n</i> ', and is $\text{LOCq}(jb+n-1)$ otherwise. Before entry with $\text{trans} = 'N'$ or ' <i>n</i> ', this array contains the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) REAL for <code>pcher2k</code> DOUBLE PRECISION for <code>pzher2k</code> Specifies the scalar <i>beta</i> .
<i>c</i>	(local) COMPLEX for <code>pcher2k</code> DOUBLE COMPLEX for <code>pzher2k</code> Array, DIMENSION (<i>lld_c</i> , $\text{LOCq}(jc+n-1)$). Before entry with <i>uplo</i> = ' <i>U</i> ' or ' <i>u</i> ', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = ' <i>L</i> ' or ' <i>l</i> ', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descc</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

c

With *uplo* = 'U' or 'u', the upper triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.
With *uplo* = 'L' or 'l', the lower triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

p?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.

Syntax

Fortran 77:

```
call pssymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic,
jc, descc)
call pdsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic,
jc, descc)
call pcsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic,
jc, descc)
call pzsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic,
jc, descc)
```

Include Files

- C: mkl_pblas.h

Description

The p?symm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B) + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(B) * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(A) is a symmetric distributed matrix, *sub(A)*=*A*(*ia*:*ia+m-1*, *ja*:*ja+m-1*), if *side* ='L', and
sub(A)=*A*(*ia*:*ia+n-1*, *ja*:*ja+n-1*), if *side* ='R'.

sub(B) and *sub(C)* are *m*-by-*n* distributed matrices.

sub(B)=*B*(*ib*:*ib+m-1*, *jb*:*jb+n-1*), *sub(C)*=*C*(*ic*:*ic+m-1*, *jc*:*jc+n-1*).

Input Parameters

side

(global) CHARACTER*1. Specifies whether the symmetric distributed matrix *sub(A)* appears on the left or right in the operation:
if *side* = 'L' or 'l', then *sub(C)* := *alpha***sub(A)* **sub(B)* +
*beta***sub(C)*;
if *side* = 'R' or 'r', then *sub(C)* := *alpha***sub(B)* **sub(A)* +
*beta***sub(C)*.

<i>uplo</i>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used: if $\text{uplo} = \text{'U'}$ or 'u' , then the upper triangular part is used; if $\text{uplo} = \text{'L'}$ or 'l' , then the lower triangular part is used.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distribute submatrix $\text{sub}(C)$, $m \geq 0$.
<i>alpha</i>	(global) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, DIMENSION (lld_a , $\text{LOCq}(ja+na-1)$). Before entry this array must contain the local pieces of the symmetric distributed matrix $\text{sub}(A)$, such that when $\text{uplo} = \text{'U'}$ or 'u' , the na -by- na upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when $\text{uplo} = \text{'L'}$ or 'l' , the na -by- na lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desc<i>a</i></i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Array, DIMENSION (lld_b , $\text{LOCq}(jb+n-1)$). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>desc<i>b</i></i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) REAL for pssymm DOUBLE PRECISION for pdsymm COMPLEX for pcsymm DOUBLE COMPLEX for pzsymm Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) REAL for pssymm DOUBLE PRECISION for pdsymm

	COMPLEX for <code>pcsymm</code> DOUBLE COMPLEX for <code>pzsymm</code> Array, DIMENSION (<code>lld_c</code> , <code>LOCq(jc+n-1)</code>). Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(C)$.
<code>ic, jc</code>	(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<code>desc_c</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

<code>c</code>	Overwritten by the m -by- n updated matrix.
----------------	---

p?syrk

Performs a rank- k update of a symmetric distributed matrix.

Syntax

```
call pssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc_c)
call pdssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc_c)
call pcssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc_c)
call pzssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, desc_c)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?syrk` routines perform a distributed matrix-matrix operation defined as

```
 $\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(A)^T + \beta \text{sub}(C),$ 
```

or

```
 $\text{sub}(C) := \alpha \text{sub}(A)^T * \text{sub}(A) + \beta \text{sub}(C),$ 
```

where:

`alpha` and `beta` are scalars,

`sub(C)` is an n -by- n symmetric distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

`sub(A)` is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$, if `trans = 'N'` or '`n`', and $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

Input Parameters

<code>uplo</code>	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ is used: If <code>uplo = 'U'</code> or ' <code>u</code> ', then the upper triangular part of the $\text{sub}(C)$ is used. If <code>uplo = 'L'</code> or ' <code>l</code> ', then the low triangular part of the $\text{sub}(C)$ is used.
<code>trans</code>	(global) CHARACTER*1. Specifies the operation:

```

if trans = 'N' or 'n', then sub(C) := alpha*sub(A)*sub(A)' +
beta*sub(C);
if trans = 'T' or 't', then sub(C) := alpha*sub(A)'*sub(A) +
beta*sub(C).

```

n

(global) INTEGER. Specifies the order of the distributed matrix *sub(C)*, *n* ≥ 0 .

k

(global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrix *sub(A)*, and on entry with *trans* = 'T' or 't', *k* specifies the number of rows of the distributed matrix *sub(A)*, *k* ≥ 0 .

alpha

(global) REAL for pssyrk
 DOUBLE PRECISION for pdssyrk
 COMPLEX for pcssyrk
 DOUBLE COMPLEX for pzssyrk
 Specifies the scalar *alpha*.

a

(local) REAL for pssyrk
 DOUBLE PRECISION for pdssyrk
 COMPLEX for pcssyrk
 DOUBLE COMPLEX for pzssyrk
 Array, DIMENSION (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix *sub(A)*.

ia, ja

(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

desca

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

beta

(global) REAL for pssyrk
 DOUBLE PRECISION for pdssyrk
 COMPLEX for pcssyrk
 DOUBLE COMPLEX for pzssyrk
 Specifies the scalar *beta*.

c

(local) REAL for pssyrk
 DOUBLE PRECISION for pdssyrk
 COMPLEX for pcssyrk
 DOUBLE COMPLEX for pzssyrk
 Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)).
 Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix *sub(C)* and its strictly lower triangular part is not referenced.
 Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix *sub(C)* and its strictly upper triangular part is not referenced.

ic, jc

(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix *sub(C)*, respectively.

descC

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *C*.

Output Parameters

c

With $uplo = 'U'$ or ''', the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.
 With $uplo = 'L'$ or ''', the lower triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?syr2k

Performs a rank-2k update of a symmetric distributed matrix.

Syntax

```
call pssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descC)
call pdssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descC)
call pcssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descC)
call pzssyr2k(uplo, trans, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c,
ic, jc, descC)
```

Include Files

- C: mkl_pblas.h

Description

The p?syr2k routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha * sub(A) * sub(B)' + alpha * sub(B) * sub(A)' + beta * sub(C),
```

or

```
sub(C) := alpha * sub(A)' * sub(B) + alpha * sub(B)' * sub(A) + beta * sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* symmetric distributed matrix, $\text{sub}(C)=C(ic:ic+n-1, jc:jc+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+k-1)$, if $trans = 'N'$ or '', and $\text{sub}(A)=A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

sub(B) is a distributed matrix, $\text{sub}(B)=B(ib:ib+n-1, jb:jb+k-1)$, if $trans = 'N'$ or '', and $\text{sub}(B)=B(ib:ib+k-1, jb:jb+n-1)$ otherwise.

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ is used:
 If $uplo = 'U'$ or ''', then the upper triangular part of the $\text{sub}(C)$ is used.
 If $uplo = 'L'$ or ''', then the low triangular part of the $\text{sub}(C)$ is used.

trans (global) CHARACTER*1. Specifies the operation:
 if $trans = 'N'$ or '', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B)' + \alpha * \text{sub}(B)' * \text{sub}(A) + \beta * \text{sub}(C);$

if *trans* = 'T' or 't', then *sub(C)* := *alpha***sub(B)*'**sub(A)* +
*alpha***sub(A)*'**sub(B)* + *beta***sub(C)*.

n
 (global) INTEGER. Specifies the order of the distributed matrix *sub(C)*, *n* ≥ 0.

k
 (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrices *sub(A)* and *sub(B)*, and on entry with *trans* = 'T' or 't', *k* specifies the number of rows of the distributed matrices *sub(A)* and *sub(B)*, *k* ≥ 0.

alpha
 (global) REAL for pssyr2k
 DOUBLE PRECISION for pdssyr2k
 COMPLEX for pcssyr2k
 DOUBLE COMPLEX for pzssyr2k
 Specifies the scalar *alpha*.

a
 (local) REAL for pssyr2k
 DOUBLE PRECISION for pdssyr2k
 COMPLEX for pcssyr2k
 DOUBLE COMPLEX for pzssyr2k
 Array, DIMENSION (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix *sub(A)*.

ia, ja
 (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

desca
 (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b
 (local) REAL for pssyr2k
 DOUBLE PRECISION for pdssyr2k
 COMPLEX for pcssyr2k
 DOUBLE COMPLEX for pzssyr2k
 Array, DIMENSION (*lld_b*, *klb*), where *klb* is LOCq(*jb*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*jb*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix *sub(B)*.

ib, jb
 (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix *sub(B)*, respectively.

descb
 (global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

beta
 (global) REAL for pssyr2k
 DOUBLE PRECISION for pdssyr2k
 COMPLEX for pcssyr2k
 DOUBLE COMPLEX for pzssyr2k
 Specifies the scalar *beta*.

c
 (local) REAL for pssyr2k
 DOUBLE PRECISION for pdssyr2k
 COMPLEX for pcssyr2k
 DOUBLE COMPLEX for pzssyr2k
 Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)).

Before entry with $\text{uplo} = \text{'U'}$ or 'u' , this array contains n -by- n upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced.

Before entry with $\text{uplo} = \text{'L'}$ or 'l' , this array contains n -by- n lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.

ic, jc

(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.

descC

(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

C

With $\text{uplo} = \text{'U'}$ or 'u' , the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

With $\text{uplo} = \text{'L'}$ or 'l' , the lower triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?tran

Transposes a real distributed matrix.

Syntax

```
call pstran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pdtran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

Include Files

- C: mkl_pblas.h

Description

The p?tran routines transpose a real distributed matrix. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*sub(A)',
```

where:

α and β are scalars,

$\text{sub}(C)$ is an m -by- n distributed matrix, $\text{sub}(C)=C(ic:ic+m-1, jc:jc+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+m-1)$.

Input Parameters

m

(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(C)$, $m \geq 0$.

n

(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(C)$, $n \geq 0$.

α

(global) REAL for pstran
DOUBLE PRECISION for pdtran
Specifies the scalar α .

a

(local) REAL for pstran
DOUBLE PRECISION for pdtran

	Array, DIMENSION (lld_a , $\text{LOCq}(ja+m-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix A .
<i>beta</i>	(global) REAL for <i>pstran</i> DOUBLE PRECISION for <i>pdtran</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) REAL for <i>pstran</i> DOUBLE PRECISION for <i>pdtran</i> Array, DIMENSION (lld_c , $\text{LOCq}(jc+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?tranu

Transposes a distributed complex matrix.

Syntax

```
call pctranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pztranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

Include Files

- C: mkl_pblas.h

Description

The p?tranu routines transpose a complex distributed matrix. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*sub(A)'
```

where:

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, $\text{sub}(C)=C(ic:ic+m-1, jc:jc+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A)=A(ia:ia+n-1, ja:ja+m-1)$.

Input Parameters

<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix $\text{sub}(C)$, $m \geq 0$.
----------	---

<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>alpha</i>	(global) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Array, DIMENSION ($l1d_a$, $\text{LOCq}(ja+m-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Array, DIMENSION ($l1d_c$, $\text{LOCq}(jc+n-1)$). This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) INTEGER. The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descC</i>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.
----------	---------------------------------------

p?tranc

Transposes a complex distributed matrix, conjugated.

Syntax

```
call pctranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
call pztranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descC)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?tranc` routines transpose a complex distributed matrix. The operation is defined as

```
 $\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{conjg}(\text{sub}(A)')$ ,
```

where:

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+m-1)`.

Input Parameters

<code>m</code>	(global) INTEGER. Specifies the number of rows of the distributed matrix <code>sub(C)</code> , $m \geq 0$.
<code>n</code>	(global) INTEGER. Specifies the number of columns of the distributed matrix <code>sub(C)</code> , $n \geq 0$.
<code>alpha</code>	(global) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Array, DIMENSION (<code>lld_a, LOCq(ja+m-1)</code>). This array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<code>ia, ja</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>beta</code>	(global) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Specifies the scalar <code>beta</code> . When <code>beta</code> is equal to zero, then <code>sub(C)</code> need not be set on input.
<code>c</code>	(local) COMPLEX for <code>pctranc</code> DOUBLE COMPLEX for <code>pztranc</code> Array, DIMENSION (<code>lld_c, LOCq(jc+n-1)</code>). This array contains the local pieces of the distributed matrix <code>sub(C)</code> .
<code>ic, jc</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>C</code> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.
<code>descC</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>C</code> .

Output Parameters

<code>c</code>	Overwritten by the updated submatrix.
----------------	---------------------------------------

p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

Syntax

```
call pstrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pdtrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pctrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pztrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- C: mkl_pblas.h

Description

The `p?trmm` routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

```
sub(B) := alpha*op(sub(A))*sub(B)
```

or

```
sub(B) := alpha*sub(B)*op(sub(A))
```

where:

`alpha` is a scalar,

`sub(B)` is an m -by- n distributed matrix, `sub(B)=B(ib:ib+m-1, jb:jb+n-1)`.

`A` is a unit, or non-unit, upper or lower triangular distributed matrix, `sub(A)=A(ia:ia+m-1, ja:ja+m-1)`, if `side = 'L' or 'l'`, and `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`, if `side = 'R' or 'r'`.

`op(sub(A))` is one of `op(sub(A)) = sub(A)`, or `op(sub(A)) = sub(A)'`, or `op(sub(A)) = conjg(sub(A)')`.

Input Parameters

<code>side</code>	(global) CHARACTER*1. Specifies whether <code>op(sub(A))</code> appears on the left or right of <code>sub(B)</code> in the operation: if <code>side = 'L' or 'l'</code> , then <code>sub(B) := alpha*op(sub(A))*sub(B);</code> if <code>side = 'R' or 'r'</code> , then <code>sub(B) := alpha*sub(B)*op(sub(A));</code>
<code>uplo</code>	(global) CHARACTER*1. Specifies whether the distributed matrix <code>sub(A)</code> is upper or lower triangular: if <code>uplo = 'U' or 'u'</code> , then the matrix is upper triangular; if <code>uplo = 'L' or 'l'</code> , then the matrix is low triangular.
<code>transa</code>	(global) CHARACTER*1. Specifies the form of <code>op(sub(A))</code> used in the matrix multiplication: if <code>transa = 'N' or 'n'</code> , then <code>op(sub(A)) = sub(A);</code> if <code>transa = 'T' or 't'</code> , then <code>op(sub(A)) = sub(A)'</code> ; if <code>transa = 'C' or 'c'</code> , then <code>op(sub(A)) = conjg(sub(A)')</code> .
<code>diag</code>	(global) CHARACTER*1. Specifies whether the matrix <code>sub(A)</code> is unit triangular: if <code>diag = 'U' or 'u'</code> then the matrix is unit triangular; if <code>diag = 'N' or 'n'</code> , then the matrix is not unit triangular.
<code>m</code>	(global) INTEGER. Specifies the number of rows of the distributed matrix <code>sub(B)</code> , $m \geq 0$.
<code>n</code>	(global) INTEGER. Specifies the number of columns of the distributed matrix <code>sub(B)</code> , $n \geq 0$.
<code>alpha</code>	(global) REAL for <code>pstrmm</code> DOUBLE PRECISION for <code>pdtrmm</code> COMPLEX for <code>pctrmm</code> DOUBLE COMPLEX for <code>pztrmm</code> Specifies the scalar <code>alpha</code> . When <code>alpha</code> is zero, then the array <code>b</code> need not be set before entry.
<code>a</code>	(local) REAL for <code>pstrmm</code> DOUBLE PRECISION for <code>pdtrmm</code>

COMPLEX for `pctrmm`
 DOUBLE COMPLEX for `pztrmm`
 Array, DIMENSION (`lld_a,ka`), where `ka` is at least `LOCq(1, ja+m-1)` when
`side = 'L'` or '`l'` and is at least `LOCq(1, ja+n-1)` when `side = 'R'` or
'`r`'.

Before entry with `uplo = 'U'` or '`u`', this array contains the local entries
 corresponding to the entries of the upper triangular distributed matrix
`sub(A)`, and the local entries corresponding to the entries of the strictly
 lower triangular part of the distributed matrix `sub(A)` is not referenced.
 Before entry with `uplo = 'L'` or '`l`', this array contains the local entries
 corresponding to the entries of the lower triangular distributed matrix
`sub(A)`, and the local entries corresponding to the entries of the strictly
 upper triangular part of the distributed matrix `sub(A)` is not referenced .
 When `diag = 'U'` or '`u`', the local entries corresponding to the diagonal
 elements of the submatrix `sub(A)` are not referenced either, but are
 assumed to be unity.

<code>ia, ja</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desc_a</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>b</code>	(local) REAL for <code>pstrmm</code> DOUBLE PRECISION for <code>pdtrmm</code> COMPLEX for <code>pctrmm</code> DOUBLE COMPLEX for <code>pztrmm</code> Array, DIMENSION (<code>lld_b, LOCq(1, jb+n-1)</code>). Before entry, this array contains the local pieces of the distributed matrix <code>sub(B)</code> .
<code>ib, jb</code>	(global) INTEGER. The row and column indices in the distributed matrix <code>B</code> indicating the first row and the first column of the submatrix <code>sub(B)</code> , respectively.
<code>desc_b</code>	(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix <code>B</code> .

Output Parameters

<code>b</code>	Overwritten by the transformed distributed matrix.
----------------	--

p?trsm

Solves a distributed matrix equation (one matrix
 operand is triangular).

Syntax

```
call pstrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pdtrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pctrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pztrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- C: `mkl_pblas.h`

Description

The p?trsm routines solve one of the following distributed matrix equations:

```
op(sub(A)) * X = alpha*sub(B),
```

or

```
X*op(sub(A)) = alpha*sub(B),
```

where:

alpha is a scalar,

X and *sub(B)* are *m*-by-*n* distributed matrices, *sub(B)=B(ib:ib+m-1, jb:jb+n-1)*;

A is a unit, or non-unit, upper or lower triangular distributed matrix, *sub(A)=A(ia:ia+m-1, ja:ja+m-1)*, if *side = 'L' or 'l'*, and *sub(A)=A(ia:ia+n-1, ja:ja+n-1)*, if *side = 'R' or 'r'*;

op(sub(A)) is one of *op(sub(A)) = sub(A)*, or *op(sub(A)) = sub(A)'*, or *op(sub(A)) = conjg(sub(A)')*.

The distributed matrix *sub(B)* is overwritten by the solution matrix *X*.

Input Parameters

<i>side</i>	(global) CHARACTER*1. Specifies whether <i>op(sub(A))</i> appears on the left or right of <i>X</i> in the equation: if <i>side = 'L' or 'l'</i> , then <i>op(sub(A)) * X = alpha*sub(B)</i> ; if <i>side = 'R' or 'r'</i> , then <i>X*op(sub(A)) = alpha*sub(B)</i> .
<i>uplo</i>	(global) CHARACTER*1. Specifies whether the distributed matrix <i>sub(A)</i> is upper or lower triangular: if <i>uplo = 'U' or 'u'</i> , then the matrix is upper triangular; if <i>uplo = 'L' or 'l'</i> , then the matrix is low triangular.
<i>transa</i>	(global) CHARACTER*1. Specifies the form of <i>op(sub(A))</i> used in the matrix equation: if <i>transa = 'N' or 'n'</i> , then <i>op(sub(A)) = sub(A)</i> ; if <i>transa = 'T' or 't'</i> , then <i>op(sub(A)) = sub(A)'</i> ; if <i>transa = 'C' or 'c'</i> , then <i>op(sub(A)) = conjg(sub(A)')</i> .
<i>diag</i>	(global) CHARACTER*1. Specifies whether the matrix <i>sub(A)</i> is unit triangular: if <i>diag = 'U' or 'u'</i> then the matrix is unit triangular; if <i>diag = 'N' or 'n'</i> , then the matrix is not unit triangular.
<i>m</i>	(global) INTEGER. Specifies the number of rows of the distributed matrix <i>sub(B)</i> , <i>m ≥ 0</i> .
<i>n</i>	(global) INTEGER. Specifies the number of columns of the distributed matrix <i>sub(B)</i> , <i>n ≥ 0</i> .
<i>alpha</i>	(global) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pctrsm DOUBLE COMPLEX for pztrsm Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.
<i>a</i>	(local) REAL for pstrsm DOUBLE PRECISION for pdtrsm COMPLEX for pctrsm

DOUBLE COMPLEX for pztrsm
Array, DIMENSION (*lld_a*, *ka*), where *ka* is at least LOCq(1, *ja+m-1*)
when *side* = 'L' or 'l' and is at least LOCq(1, *ja+n-1*) when *side* = 'R' or 'r'.
Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.
Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced . When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, ja
(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desc_a
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *A*.

b
(local) REAL for pstrsm
DOUBLE PRECISION for pdtrsm
COMPLEX for pcptrsm
DOUBLE COMPLEX for pztrsm
Array, DIMENSION (*lld_b*, LOCq(1, *jb+n-1*)).
Before entry, this array contains the local pieces of the distributed matrix sub(*B*).

ib, jb
(global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

desc_b
(global and local) INTEGER array of dimension 9. The array descriptor of the distributed matrix *B*.

Output Parameters

b Overwritten by the solution distributed matrix *x*.

Partial Differential Equations Support

13

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Library (see [Poisson Library Routines](#)).

Poisson Library is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the one that the Poisson Library provides. As it may be hard enough to modify the original code so as to make it work with Poisson Library, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Library routines can be called from C and Fortran 90, although the interfaces description uses C convention. Fortran 90 users can find routine calls specifics in the "[Calling PDE Support Routines from Fortran 90](#)" section.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter "[Fast Fourier Transforms](#)", Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this manual, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

To describe the Intel MKL TT interface, the C convention is used. Fortran users should refer to [Calling PDE Support Routines from Fortran 90](#).

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to the "[FFTW to Intel® MKL Wrappers for FFTW 3.x](#)" section in [Appendix F](#) for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, k = 1, \dots, n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, i = 1, \dots, n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, k = 1, \dots, n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, i = 1, \dots, n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

Forward cosine transform

$$F(k) = \frac{1}{n} [f(0) + f(n) \cos k\pi] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, k = 0, \dots, n$$

Backward cosine transform

$$f(i) = \frac{1}{2} [F(0) + F(n) \cos i\pi] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, i = 0, \dots, n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, k = 0, \dots, n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, i = 0, \dots, n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, k = 1, \dots, n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos \frac{(2k-1)(2i-1)\pi}{4n}, i = 1, \dots, n$$

NOTE The size of the transform n can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table "TT Interface Routines"](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

TT Interface Routines

Routine	Description
?_init_trig_transform	Initializes basic data structures of Trigonometric Transforms.
?_commit_trig_transform	Checks consistency and correctness of user-defined data as well as creates a data structure to be used by Intel MKL FFT interface ¹ .

Routine	Description
?_forward_trig_transform	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
?_backward_trig_transform	Cleans the memory used by a data structure needed for calling FFT interface ¹ .
free_trig_transform	

¹TT routines call Intel MKL FFT interface for better performance.

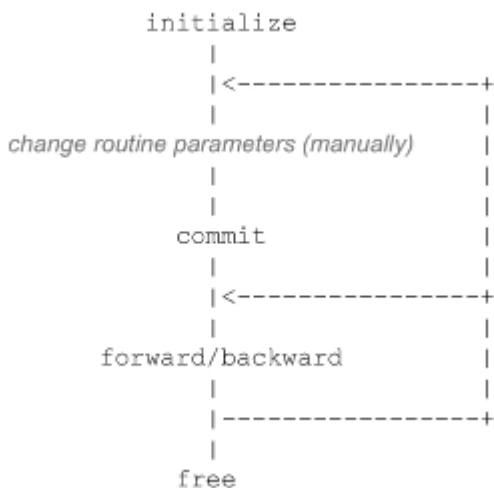

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in [Table "TT Interface Routines"](#).

NOTE Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking TT Interface Routines"](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

Typical Order of Invoking TT Interface Routines

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```

...
d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f ! If you want to preserve the data stored in f,
save them before this place in your code */
d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...
  
```

You can find examples of Fortran 90 and C code that use TT interface routines to solve one-dimensional Helmholtz problem in the `examples\pdettf\source` and `examples\pdettc\source` folders of your Intel MKL directory.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the `examples\pdettf\source` and `examples\pdettc\source` folders of your Intel MKL directory).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

NOTE If you need a copy of your input data arrays, save them yourself.

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform(int *n, int *tt_type, int ipar[], double dpar[], int *stat);
void s_init_trig_transform(int *n, int *tt_type, int ipar[], float spar[], int *stat);
```

Include Files

- FORTRAN 90: `mkl_trig_transforms.f90`
- C: `mkl.h`

Input Parameters

<i>n</i>	<i>int*</i> . Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size $n+1$ for all but staggered2 transforms. Staggered2 transforms require the vector of size n .
<i>tt_type</i>	<i>int*</i> . Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

Output Parameters

<i>ipar</i>	<i>int array</i> of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	<i>double array</i> of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	<i>float array</i> of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.
<i>stat</i>	<i>int*</i> . Contains the routine completion status, which is also written to <i>ipar[6]</i> . The status should be 0 to proceed to other TT routines.

Description

The `?_init_trig_transform` routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of *ipar* and *dpar* (*spar*) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array *ipar*. In the *dpar* or *spar* array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. You can skip calling the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task.

`?_commit_trig_transform`

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],  
double dpar[], int *stat);  
  
void s_commit_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],  
float spar[], int *stat);
```

Include Files

- FORTRAN 90: `mkl_trig_transforms.f90`

- C: mkl.h

Input Parameters

<i>f</i>	double for <i>d_commit_trig_transform</i> , float for <i>s_commit_trig_transform</i> , array of size <i>n</i> for staggered2 transforms and of size <i>n+1</i> for all other transforms, where <i>n</i> is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:
	<ul style="list-style-type: none"> • <i>f[0]</i> and <i>f[n]</i> for sine transforms • <i>f[n]</i> for staggered cosine transforms • <i>f[0]</i> for staggered sine transforms.
	Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.
<i>ipar</i>	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.
<i>dpar</i>	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>spar</i>	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>stat</i>	int*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of *d_commit_trig_transform*, and *spar* in case of *s_commit_trig_transform*. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine performs only a basic check for correctness and

consistency of the parameters. If you are going to modify parameters of TT routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_trig_transform`, the `?_commit_trig_transform` routine is mandatory, and you cannot skip calling it in your code.

Return Values

<code>stat= 11</code>	The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <code>ipar[6]=0</code> if you are sure that the parameters are correct.
<code>stat= 10</code>	The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <code>ipar[6]=0</code> if you are sure that the parameters are correct.
<code>stat= 1</code>	The routine produced some warnings. You may proceed with computations by assigning <code>ipar[6]=0</code> if you are sure that the parameters are correct.
<code>stat= 0</code>	The routine completed the task normally.
<code>stat= -100</code>	The routine stopped for any of the following reasons: <ul style="list-style-type: none"> • An error in the user's data was encountered. • Data in <code>ipar</code>, <code>dpar</code> or <code>spar</code> parameters became incorrect and/or inconsistent as a result of modifications.
<code>stat= -1000</code>	The routine stopped because of an FFT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.

NOTE Although positive values of `stat` usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve `stat=0`.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],  
double dpar[], int *stat);  
  
void s_forward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],  
float spar[], int *stat);
```

Include Files

- FORTRAN 90: `mkl_trig_transforms.f90`
- C: `mkl.h`

Input Parameters

<code>f</code>	double for <code>d_forward_trig_transform</code> ,
----------------	--

`float for s_forward_trig_transform,`
 array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- $f[0]$ and $f[n]$ for sine transforms
- $f[n]$ for staggered cosine transforms
- $f[0]$ for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the [Poisson Library Routines](#) section), which the TT interface is primarily designed for.

handle

`DFTI_DESCRIPTOR_HANDLE*`. The data structure used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms").

ipar

`int` array of size 128. Contains integer data needed for Trigonometric Transform computations.

dpar

`double` array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.

spar

`float` array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

f

Contains the transformed vector on output.

ipar

Contains integer data needed for Trigonometric Transform computations. On output, $ipar[6]$ is updated with the *stat* value.

stat

`int*`. Contains the routine completion status, which is also written to $ipar[6]$.

Description

The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem n , which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

NOTE If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_forward_trig_transform` routine.

Return Values

stat= 0

The routine completed the task normally.

stat= -100

The routine stopped for any of the following reasons:

- An error in the user's data was encountered.

- Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.

stat= -1000

The routine stopped because of an FFT interface error.

stat= -10000

The routine stopped because its commit step failed to complete or the parameter *ipar*[0] was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],
double dpar[], int *stat);

void s_backward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],
float spar[], int *stat);
```

Include Files

- FORTRAN 90: mkl_trig_transforms.f90
- C: mkl.h

Input Parameters

f

double for *d_backward_trig_transform*,
float for *s_backward_trig_transform*,
array of size *n* for staggered2 transforms and of size *n*+1 for all other
transforms, where *n* is the size of the problem. On input, contains data
vector to be transformed. Note that the following values should be 0.0 up to
rounding errors:

- *f*[0] and *f*[*n*] for sine transforms
- *f*[*n*] for staggered cosine transforms
- *f*[0] for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the
computations for sine transforms may be wrong. The above restrictions
meet the requirements of the Poisson Library (described in the [Poisson
Library Routines](#) section), which the TT interface is primarily designed for.

handle

DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT
interface (for details, refer to section "FFT Functions" in chapter "Fast
Fourier Transforms").

ipar

int array of size 128. Contains integer data needed for Trigonometric
Transform computations.

dpar

double array of size $5n/2+2$. Contains double-precision data needed for
Trigonometric Transform computations.

spar

float array of size $5n/2+2$. Contains single-precision data needed for
Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.
<i>stat</i>	<i>int*</i> . Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The routine computes the backward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_backward_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

NOTE If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -100	The routine stopped for any of the following reasons: <ul style="list-style-type: none"> • An error in the user's data was encountered. • Data in <i>ipar</i>, <i>dpar</i> or <i>spar</i> parameters became incorrect and/or inconsistent as a result of modifications.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -10000	The routine stopped because its commit step failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], int *stat);
```

Include Files

- FORTRAN 90: `mkl_trig_transforms.f90`
- C: `mkl.h`

Input Parameters

<i>ipar</i>	<i>int</i> array of size 128. Contains integer data needed for Trigonometric Transform computations.
-------------	--

handle DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms").

Output Parameters

handle The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.

ipar Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.

stat int*. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The `free_trig_transform` routine cleans the memory used by the *handle* structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -99999	The routine failed to complete the task.

Common Parameters

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE Initial values are assigned to the array parameters by the appropriate `?_init_trig_transform` and `?_commit_trig_transform` routines.

ipar int array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in [Table "Elements of the ipar Array"](#):

Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The <code>?_init_trig_transform</code> routine sets <i>ipar[0]=n</i> , and all subsequently called TT routines use <i>ipar[0]</i> as the size of the transform.
1	Contains error messaging options: <ul style="list-style-type: none"> • <i>ipar[1]=-1</i> indicates that all error messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[1]=0</i> indicates that no error messages will be printed. • <i>ipar[1]=1</i> (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen). In case of errors, each TT routine assigns a non-zero value to <i>stat</i> regardless of the <i>ipar[1]</i> setting.

Index	Description
2	<p>Contains warning messaging options:</p> <ul style="list-style-type: none"> • <i>ipar[2]</i>=-1 indicates that all warning messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[2]</i>=0 indicates that no warning messages will be printed. • <i>ipar[2]</i>=1 (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen). <p>In case of warnings, the <i>stat</i> parameter will acquire a non-zero value regardless of the <i>ipar[2]</i> setting.</p>
3 through 4	Reserved for future use.
5	<p>Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <i>ipar[5]</i>=<i>tt_type</i>, and all subsequently called TT routines use <i>ipar[5]</i> as the type of the transform.</p>
6	<p>Contains the <i>stat</i> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <i>stat</i>=0.</p>
7	<p>Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <i>dpar</i> (<i>spar</i>) and <i>handle</i>. <i>ipar[7]</i>=0 indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1.</p> <p>The possibility to check correctness and consistency of input data without initializing data structures <i>dpar</i>, <i>spar</i> and <i>handle</i> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <i>ipar[7]</i> gives only if you are sure to have supplied proper tolerance value in the <i>dpar</i> or <i>spar</i> array. Otherwise, avoid tuning this parameter.</p>
8	<p>Contains message style options for TT routines. If <i>ipar[8]</i>=0 then TT routines print all error and warning messages in Fortran-style notations. Otherwise, TT routines print the messages in C-style notations. The default value is 1.</p> <p>When selecting between these notations, mind that by default, numbering of elements in C arrays starts from 0 and in Fortran, it starts from 1. For example, for a C-style message "parameter <i>ipar[0]</i>=3 should be an even integer", the corresponding Fortran-style message will be "parameter <i>ipar(1)</i>=3 should be an even integer". The use of <i>ipar[8]</i> enables you to view messages in a more convenient style.</p>
9	<p>Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Poisson Library. The default value is 1. You are highly recommended not to alter this value. See also Caveat on Parameter Modifications.</p>
10	<p>Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in the "FFTW to Intel® MKL Wrappers for FFTW 3.x" section in Appendix F. See also Caveat on Parameter Modifications.</p>
11 through 127	Reserved for future use.

NOTE You may declare the *ipar* array in your code as `int ipar[11]`. However, for compatibility with later versions of Intel MKL TT interface, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	double array of size $5n/2+2$, holds data needed for double-precision routines to perform TT computations. This array is initialized in the <code>d_init_trig_transform</code> and <code>d_commit_trig_transform</code> routines.
<i>spar</i>	float array of size $5n/2+2$, holds data needed for single-precision routines to perform TT computations. This array is initialized in the <code>s_init_trig_transform</code> and <code>s_commit_trig_transform</code> routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table "Elements of the *dpar* and *spar* Arrays":

Elements of the *dpar* and *spar* Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate <code>?_commit_trig_transform</code> routine. For a staggered cosine or a sine transform, $f[n]$ should be equal to 0.0 and for a staggered sine or a sine transform, $f[0]$ should be equal to 0.0. The <code>?_commit_trig_transform</code> routine checks whether absolute values of these parameters are below $dpar[0]*n$ or $spar[0]*n$, depending on the routine precision. To suppress warnings resulting from tolerance checks, set <i>dpar[0]</i> or <i>spar[0]</i> to a sufficiently large number.
1	Reserved for future use.
2 through $5n/2+1$	Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform <i>tt_type</i> , set up in the <code>?_commit_trig_transform</code> routine: <ul style="list-style-type: none"> If <i>tt_type</i>=<code>MKL_SINE_TRANSFORM</code>, the transform uses only the first $n/2$ array elements, which contain tabulated sine values. If <i>tt_type</i>=<code>MKL_STAGGERED_SINE_TRANSFORM</code>, the transform uses only the first $3n/2$ array elements, which contain tabulated sine and cosine values. If <i>tt_type</i>=<code>MKL_STAGGERED2_SINE_TRANSFORM</code>, the transform uses all the $5n/2$ array elements, which contain tabulated sine and cosine values. If <i>tt_type</i>=<code>MKL_COSINE_TRANSFORM</code>, the transform uses only the first n array elements, which contain tabulated cosine values. If <i>tt_type</i>=<code>MKL_STAGGERED_COSINE_TRANSFORM</code>, the transform uses only the first $3n/2$ elements, which contain tabulated sine and cosine values. If <i>tt_type</i>=<code>MKL_STAGGERED2_COSINE_TRANSFORM</code>, the transform uses all the $5n/2$ elements, which contain tabulated sine and cosine values.

NOTE To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip calling the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays.

Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the TT language-specific header files to include in their code. Currently, the following of them are available:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_trig_transforms.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE Use of the Intel MKL TT software without including one of the above header files is not supported.

C-specific Header File

The C-specific header file defines the following function prototypes:

```
void d_init_trig_transform(int *, int *, int *, double *, int *);
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);

void s_init_trig_transform(int *, int *, int *, float *, int *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);
void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, int *, int *);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes:

```
SUBROUTINE D_INIT_TRIG_TRANSFORM(n, tt_type, ipar, dpar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_INIT_TRIG_TRANSFORM
```

```
SUBROUTINE D_COMMIT_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_COMMIT_TRIG_TRANSFORM
```

```
SUBROUTINE D_FORWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_FORWARD_TRIG_TRANSFORM
```

```
SUBROUTINE D_BACKWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_BACKWARD_TRIG_TRANSFORM
```

```
SUBROUTINE S_INIT_TRIG_TRANSFORM(n, tt_type, ipar, spar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_INIT_TRIG_TRANSFORM
```

```
SUBROUTINE S_COMMIT_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(OUT) :: stat
```

Fortran 90 specifics of the TT routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Poisson Library Routines

In addition to Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel® MKL supports the Poisson Library interface, referred to as PL interface. The interface implements a group of routines (PL routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems being solved are defined more exactly in the [Poisson Library Implemented](#) subsection. The PL interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The interface can adjust style of error and warning messages to C or Fortran notations by setting up a dedicated parameter. This adds convenience to debugging, because users can read information in the way that is natural for their code. The Intel MKL PL interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

To describe the Intel MKL PL interface, the C convention is used. Fortran usage specifics can be found in the [Calling PDE Support Routines from Fortran 90](#) section.

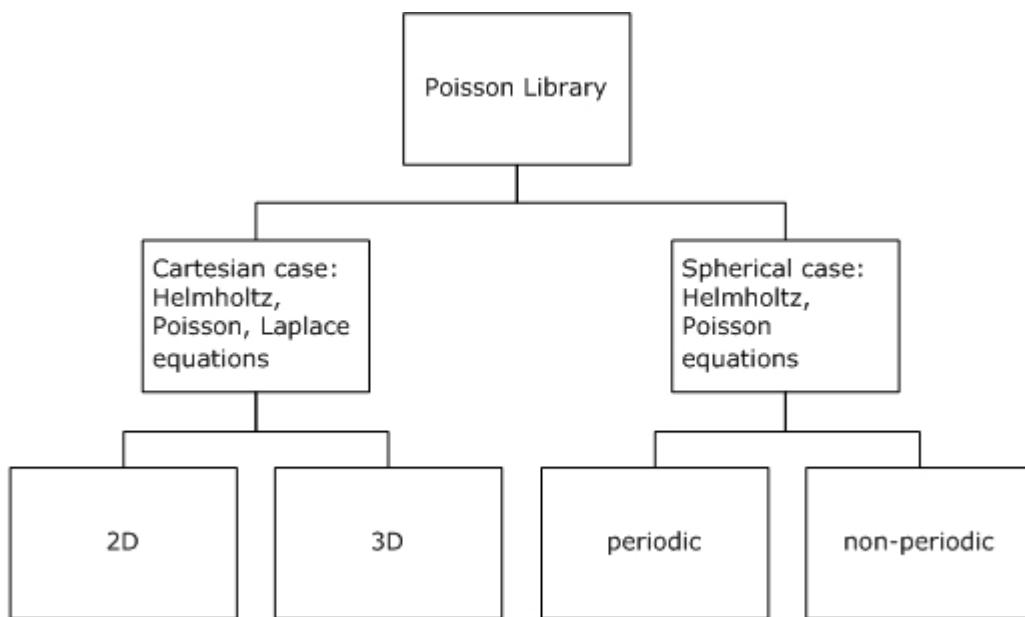

NOTE Fortran users should mind that respective array indices in Fortran increase by 1.

Poisson Library Implemented

PL routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure "Structure of the Poisson Library"](#) shows the general structure of the Poisson Library.

Structure of the Poisson Library

Sections below provide details of the problems that can be solved using Intel MKL PL.

Two-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$ on a Cartesian plane:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y\}, bd_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y\}, bd_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The wildcard "+" may stand for any of the symbols a_x, b_x, a_y, b_y , so that bd_+ denotes any of the above boundaries.

The PL interface description uses the following notation for boundaries of a rectangular domain $a_\phi < \phi < b_\phi$, $a_\theta < \theta < b_\theta$ on a sphere $0 \leq \phi \leq 2\pi$, $0 \leq \theta \leq \pi$:

$$bd_a_\phi = \{\phi = a_\phi, a_\theta \leq \theta \leq b_\theta\}, bd_b_\phi = \{\phi = b_\phi, a_\theta \leq \theta \leq b_\theta\}$$

$$bd_a_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = a_\theta\}, bd_b_\theta = \{a_\phi \leq \phi \leq b_\phi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols $a_\phi, b_\phi, a_\theta, b_\theta$, so that $bd_~$ denotes any of the above boundaries.

Two-dimensional (2D) Helmholtz problem on a Cartesian plane

The 2D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), q = const \geq 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$$n = -x \text{ on } bd_a_x, n = x \text{ on } bd_b_x,$$

$$n = -y \text{ on } bd_a_y, n = y \text{ on } bd_b_y.$$

Two-dimensional (2D) Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y)=0$. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle $a_x < x < b_x, a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ .

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, \quad q = const \geq 0,$$

$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle that is, a domain bounded by angles $a_\phi \leq \phi \leq b_\phi, a_\theta \leq \theta \leq b_\theta$, with boundary conditions for particular domains listed in [Table "Details of Helmholtz Problem on a Sphere"](#).

Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\phi - a_\phi < 2\pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary $bd_ \sim$	<i>non-periodic</i>
Where $a_\phi = 0, b_\phi = 2\pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries bd_a_θ and bd_b_θ	<i>periodic</i>
Entire sphere, that is, $a_\phi = 0, b_\phi = 2\pi, a_\theta = 0$, and $b_\theta = \pi$	Boundary condition $\left(\sin \theta \frac{\partial u}{\partial \theta} \right)_{\theta \rightarrow 0}^{_{\theta \rightarrow \pi}} = 0$ at the poles.	<i>periodic</i>

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \quad \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle $a_\phi \leq \phi \leq b_\phi$, $a_\theta \leq \theta \leq b_\theta$ in cases listed in [Table "Details of Helmholtz Problem on a Sphere"](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, a uniform mesh is built in the rectangular domain:

$$\begin{aligned} & \left\{ x_i = a_x + i h_x, y_j = a_y + j h_y \right\}, \\ & i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y} \end{aligned}$$

in the Cartesian case and

$$\begin{aligned} & \left\{ \phi_i = a_\phi + i h_\phi, \theta_j = a_\theta + j h_\theta \right\}, \\ & i = 0, \dots, n_\phi, j = 0, \dots, n_\theta, h_\phi = \frac{b_\phi - a_\phi}{n_\phi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta} \end{aligned}$$

in the spherical case.

Poisson Library uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i, y_j) provided that the user knows the values of the right-hand side $f(x, y)$ in these points and the values of the appropriate boundary functions $G(x, y)$ and/or $g(x, y)$ in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (ϕ_i, θ_j) provided that the user knows the values of the right-hand side $f(\phi, \theta)$ in these points.

NOTE The number of mesh intervals n_ϕ in the ϕ direction of a spherical mesh must be even in the periodic case. The current implementation of the Poisson Library does not support meshes with the number of intervals that does not meet this condition.

Three-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$:

$$bd_a_x = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, bd_b_x = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}$$

$$bd_a_y = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, bd_b_y = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\}$$

$$bd_a_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}, bd_b_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}.$$

The wildcard "+" may stand for any of the symbols $a_x, b_x, a_y, b_y, a_z, b_z$, so that bd_+ denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), q = const \geq 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y, z) = G(x, y, z)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd_a_x, n = x \text{ on } bd_b_x,$$

$$n = -y \text{ on } bd_a_y, n = y \text{ on } bd_b_y,$$

$$n = -z \text{ on } bd_a_z, n = z \text{ on } bd_b_z.$$

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$ with Dirichlet or Neumann boundary condition on each boundary bd_+ .

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y, z)=0$. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet or Neumann boundary condition on each boundary bd_+ .

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh is built in the parallelepiped domain

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\}$$

where

$$i = 0, \dots, n_x, j = 0, \dots, n_y, k = 0, \dots, n_z$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}$$

The Poisson Library uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k) , provided that the user knows the values of the right-hand side $f(x, y, z)$ in these points and the values of the appropriate boundary functions $G(x, y, z)$ and/or $g(x, y, z)$ in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking PL Routines

NOTE This description always considers the solution process for the Helmholtz problem, because Fast Poisson Solver and Fast Laplace Solver are special cases of Fast Helmholtz Solver (see [Poisson Library Implemented](#)).

Computation of a solution of the Helmholtz problem using the PL interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table "PL Interface Routines"](#) lists the routines and briefly describes their purpose.

Most PL routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names. The routines for Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "2D" and "3D". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "p" and "np"

PL Interface Routines

Routine	Description
?_init_Helmholtz_2D/?_init_Helmholtz_3D/ ?_init_sph_p/?_init_sph_np	Initializes basic data structures of Poisson Library for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/ ?_commit_sph_p/?_commit_sph_np	Checks consistency and correctness of user's data, creates and initializes data structures to be used by the Intel MKL FFT interface ¹ , as well as other data structures needed for the solver.
?_Helmholtz_2D/?_Helmholtz_3D/ ?_sph_p/?_sph_np	Computes an approximate solution of 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Library Implemented) specified by the parameters.
free_Helmholtz_2D/free_Helmholtz_3D/ free_sph_p/ free_sph_np	Cleans the memory used by the data structures needed for calling the Intel MKL FFT interface ¹ .

¹ PL routines call the Intel MKL FFT interface for better performance.

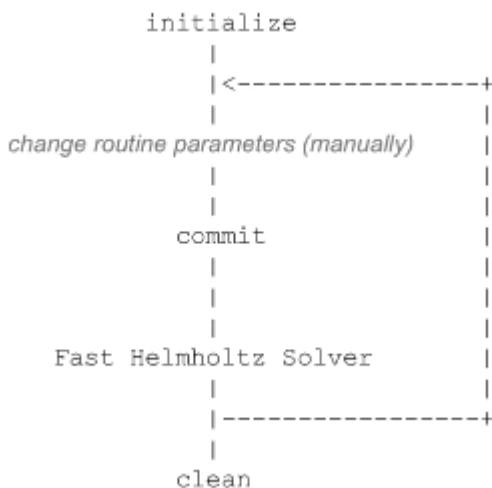

To find an approximate solution of Helmholtz problem only once, the Intel MKL PL interface routines are normally invoked in the order in which they are listed in [Table "PL Interface Routines"](#).

NOTE Though the order of invoking PL routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in Figure "Typical Order of Invoking PL Routines" indicates the typical order in which PL routines can be invoked in a general case.

Typical Order of Invoking PL Routines

A general scheme of using PL routines for double-precision computations in a 3D Cartesian case is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a 2D Cartesian case differs from the one below in the set of routine parameters and the ending of routine names: "2D" instead of "3D".

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, BCtype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to keep the data stored
in f,
save it before the function call below */

d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);

d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar, &stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);

/* here you may clean the memory used by f, dpar, ipar */
...
...
```

A general scheme of using PL routines for double-precision computations in a spherical periodic case is shown below. Similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a spherical non-periodic case differs from the one below in the set of routine parameters and the ending of routine names: "np" instead of "p".

```
...
d_init_sph_p(&ap,&bp,&at,&bt,&np,&nt,&q,ipar,dpar,&stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to
keep the data stored in f, save it before the function call below */

d_commit_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
d_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
free_sph_p(&handle_s,&handle_c,ipar,&stat);

/* here you may clean the memory used by f, dpar, ipar */
...
...
```

You can find examples of Fortran 90 and C code that use PL routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the `examples\pdepoissonf\source` and `examples\pdepoissons\source` folders of your Intel MKL directory.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the `examples\pdepoissonf\source` and `examples\pdepoissons\source` folders of your Intel MKL directory).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel(R) MKL User's Guide*.

Routine Options

All PL routines use parameters for passing various options to the routines. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

PL routines take arrays of user data as input. For example, user arrays are passed to the routine `d_Helmholtz_3D` to compute an approximate solution to 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL PL routines do not make copies of user input arrays.

NOTE If you need a copy of your input data arrays, save them yourself.

PL Routines for the Cartesian Solver

The section gives detailed description of Cartesian PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, 2D and 3D, are described together.

NOTE Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

PL routines call the Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_Helmholtz_2D/?_init_Helmholtz_3D

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```
void d_init_Helmholtz_2D(double* ax, double* bx, double* ay, double* by, int* nx, int* ny, char* BCtype, double* q, int* ipar, double* dpar, int* stat);
void s_init_Helmholtz_2D(float* ax, float* bx, float* ay, float* by, int* nx, int* ny, char* BCtype, float* q, int* ipar, float* spar, int* stat);
void d_init_Helmholtz_3D(double* ax, double* bx, double* ay, double* by, double* az, double* bz, int* nx, int* ny, int* nz, char* BCtype, double* q, int* ipar, double* dpar, int* stat);
void s_init_Helmholtz_3D(float* ax, float* bx, float* ay, float* by, float* az, float* bz, int* nx, int* ny, int* nz, char* BCtype, float* q, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<code>ax</code>	<code>double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D,</code> <code>float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.</code> <code>The coordinate of the leftmost boundary of the domain along x-axis.</code>
<code>bx</code>	<code>double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D,</code>

	float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along x-axis.
ay	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along y-axis.
by	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along y-axis.
az	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
bz	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
nx	int*. The number of mesh intervals along x-axis.
ny	int*. The number of mesh intervals along y-axis.
nz	int*. The number of mesh intervals along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
BCtype	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ?_init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition) or 'D' (Dirichlet boundary condition). Types of boundary conditions for the boundaries should be specified in the following order: bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz. Boundary condition types for the last two boundaries should be specified only in the 3D case.
q	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D . The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of q to 0.

Output Parameters

ipar	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
dpar	double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
spar	float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
stat	int*. Routine completion status, which is also written to ipar[0]. The status should be 0 to proceed to other PL routines.

Description

The ?_init_Helmholtz_2D/?_init_Helmholtz_3D routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a ?_init_Helmholtz_2D/?_init_Helmholtz_3D routine use values of the ipar, dpar and spar array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING Data structures initialized and created by 2D/3D flavors of the routine cannot be used by 3D/2D flavors of any PL routines, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

<code>stat= 0</code>	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <code>stat</code> value.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

?_commit_Helmholtz_2D/?_commit_Helmholtz_3D

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, double* dpar, int* stat);
void s_commit_Helmholtz_2D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float*
bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, float* spar, int* stat);
void d_commit_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, int* ipar, double* dpar, int* stat);
void s_commit_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float*
bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<code>f</code>	double* for <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> , float* for <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> . Contains the right-hand side of the problem packed in a single vector. The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, the value of the right-hand side in the mesh point (i, j) is stored in $f[i + j*(nx+1)]$. The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in $f[i + j*(nx+1) + k*(nx+1)*(ny+1)]$. Note that to solve the Laplace problem, you should set all the elements of the array <code>f</code> to 0. Note also that the array <code>f</code> may be altered by the routine. To preserve the vector, save it in another memory location.
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

<i>dpar</i>	double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>bd_ax</i>	<p><code>double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,</code> <code>float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.</code></p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along <i>x</i>-axis.</p> <p>For <code>?_commit_Helmholtz_2D</code>, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index <i>j</i> is placed in <code>bd_ax[j]</code>.</p> <p>For <code>?_commit_Helmholtz_3D</code>, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in <code>bd_ax[j+k*(ny+1)]</code>.</p>
<i>bd_bx</i>	<p><code>double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,</code> <code>float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.</code></p> <p>Contains values of the boundary condition on the rightmost boundary of the domain along <i>x</i>-axis.</p> <p>For <code>?_commit_Helmholtz_2D</code>, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of <code>BCtype[1]</code> is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of <code>BCtype[1]</code> is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index <i>j</i> is placed in <code>bd_bx[j]</code>.</p> <p>For <code>?_commit_Helmholtz_3D</code>, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of <code>BCtype[1]</code> is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. In case of the Neumann boundary condition (value of <code>BCtype[1]</code> is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny, k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in <code>bd_bx[j+k*(ny+1)]</code>.</p>
<i>bd_ay</i>	<p><code>double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,</code> <code>float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.</code></p> <p>Contains values of the boundary condition on the leftmost boundary of the domain along <i>y</i>-axis.</p> <p>For <code>?_commit_Helmholtz_2D</code>, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of <code>BCtype[2]</code> is 'D'), it contains values of the function $G(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of <code>BCtype[2]</code> is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index <i>i</i> is placed in <code>bd_ay[i]</code>.</p>

For `?_commit_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[2]` is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[2]` is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_ay[i+k*(nx+1)]`.

`bd_by`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

Contains values of the boundary condition on the rightmost boundary of the domain along y -axis.

For `?_commit_Helmholtz_2D`, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of `BCtype[3]` is 'D'), it contains values of the function $G(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of `BCtype[3]` is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in `bd_by[i]`.

For `?_commit_Helmholtz_3D`, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of `BCtype[3]` is 'D'), it contains values of the function $G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of `BCtype[3]` is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in `bd_by[i+k*(nx+1)]`.

`bd_az`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i + j*(nx+1)]`.

`bd_bz`

`double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D,`
`float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.`

This parameter is needed only for `?_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along z -axis.

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i + j*(nx+1)]`.

Output Parameters

`f`

Vector of the right-hand side of the problem. Possibly, altered on output.

<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<i>xhandle</i> , <i>yhandle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms"). <i>yhandle</i> is used only by <code>?_commit_Helmholtz_3D</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines check consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize data structures *xhandle*, *yhandle* as well as arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications section](#). Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, the routines `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` are mandatory, and you cannot skip calling them in your code. Values of *ax*, *bx*, *ay*, *by*, *az*, *bz*, *nx*, *ny*, *nz*, and *BCtype* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
<i>stat</i> = -10000	The routine stopped because the initialization failed to complete or the parameter <i>ipar[0]</i> was altered by mistake.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

?_Helmholtz_2D/?_Helmholtz_3D

Computes the solution of 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay, double* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, double* dpar, int* stat);
void s_Helmholtz_2D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float* bd_by, float* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, float* spar, int* stat);
```

```

void d_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay, double*
bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, int* ipar, double* dpar, int* stat);

void s_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float* bd_by,
float* bd_az, float* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE*
yhandle, int* ipar, float* spar, int* stat);

```

Include Files

- FORTRAN 90: mkl_poisson.f90
- C: mkl.h

Input Parameters

<i>f</i>	double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D. Contains the right-hand side of the problem packed in a single vector and modified by the appropriate ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector for the 2D problem is $(nx+1)*(ny+1)$. In this case, value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(nx+1)]$. The size of the vector for the 3D problem is $(nx+1)*(ny+1)*(nz+1)$. In this case, value of the right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(nx+1)+k*(nx+1)*(ny+1)]$.
<i>xhandle</i> , <i>yhandle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). <i>yhandle</i> is used only by ?_Helmholtz_3D.
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters)
<i>spar</i>	float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
<i>bd_ax</i>	double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along <i>x</i> -axis. For ?_Helmholtz_2D, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of BCtype[0] is 'D'), it contains values of the function $G(ax, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of BCtype[0] is 'N'), it contains values of the function $g(ax, y_j)$, $j=0, \dots, ny$. The value corresponding to the index <i>j</i> is placed in <i>bd_ax</i> [<i>j</i>]. For ?_Helmholtz_3D, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of BCtype[0] is 'D'), it contains values of the function $G(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of BCtype[0] is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in <i>bd_ax</i> [<i>j+k*(ny+1)</i>].

<code>bd_bx</code>	<pre>double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D.</pre> <p>Contains values of the boundary condition on the rightmost boundary of the domain along x-axis. For $?_Helmholtz_2D$, the size of the array is $ny+1$. In case of the Dirichlet boundary condition (value of $BCtype[1]$ is 'D'), it contains values of the function $G(bx, y_j)$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of $BCtype[1]$ is 'N'), it contains values of the function $g(bx, y_j)$, $j=0, \dots, ny$. The value corresponding to the index j is placed in $bd_bx[j]$. For $?_Helmholtz_3D$, the size of the array is $(ny+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCtype[1]$ is 'D'), it contains values of the function $G(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCtype[1]$ is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, $j=0, \dots, ny$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in $bd_bx[j+k*(ny+1)]$.</p>
<code>bd_ay</code>	<pre>double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D.</pre> <p>Contains values of the boundary condition on the leftmost boundary of the domain along y-axis. For $?_Helmholtz_2D$, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of $BCtype[2]$ is 'D'), it contains values of the function $G(x_i, ay)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of $BCtype[2]$ is 'N'), it contains values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in $bd_ay[i]$. For $?_Helmholtz_3D$, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCtype[2]$ is 'D'), it contains values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCtype[2]$ is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in $bd_ay[i+k*(nx+1)]$.</p>
<code>bd_by</code>	<pre>double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D.</pre> <p>Contains values of the boundary condition on the rightmost boundary of the domain along y-axis. For $?_Helmholtz_2D$, the size of the array is $nx+1$. In case of the Dirichlet boundary condition (value of $BCtype[3]$ is 'D'), it contains values of the function $G(x_i, by)$, $i=0, \dots, nx$. In case of the Neumann boundary condition (value of $BCtype[3]$ is 'N'), it contains values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index i is placed in $bd_by[i]$. For $?_Helmholtz_3D$, the size of the array is $(nx+1)*(nz+1)$. In case of the Dirichlet boundary condition (value of $BCtype[3]$ is 'D'), it contains values of the function $G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. In case of the Neumann boundary condition (value of $BCtype[3]$ is 'N'), it contains the values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (i, k) is placed in $bd_by[i+k*(nx+1)]$.</p>
<code>bd_az</code>	<pre>double* for d_Helmholtz_2D/d_Helmholtz_3D, float* for s_Helmholtz_2D/s_Helmholtz_3D.</pre> <p>This parameter is needed only for $?_Helmholtz_3D$. Contains values of the boundary condition on the leftmost boundary of the domain along z-axis.</p>

The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[4]` is 'D'), it contains values of the function $G(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[4]` is 'N'), it contains the values of the function $g(x_i, y_j, az)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_az[i + j*(nx+1)]`.

`bd_bz`

```
double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.
```

This parameter is needed only for `?_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along z -axis. The size of the array is $(nx+1)*(ny+1)$. In case of the Dirichlet boundary condition (value of `BCtype[5]` is 'D'), it contains values of the function $G(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. In case of the Neumann boundary condition (value of `BCtype[5]` is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, $i=0, \dots, nx$, $j=0, \dots, ny$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in `bd_bz[i + j*(nx+1)]`.

NOTE To avoid wrong computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>xhandle</code> , <code>yhandle</code>	Data structures used by the Intel MKL FFT interface.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<code>dpar</code>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<code>spar</code>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters .
<code>stat</code>	<code>int*</code> . Routine completion status, which is also written to <code>ipar[0]</code> . The status should be 0 to proceed to other PL routines.

Description

The `Helmholtz_2D-Helmholtz_3D` routines compute the approximate solution of Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The `f` parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of `ax`, `bx`, `ay`, `by`, `az`, `bz`, `nx`, `ny`, `nz`, and `BCtype` are passed to each of the routines with the `ipar` array and defined in the previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

<code>stat= 1</code>	The routine completed without errors and produced some warnings.
<code>stat= 0</code>	The routine successfully completed the task.

<code>stat= -2</code>	The routine stopped because division by zero occurred. It usually happens if the data in the <code>dpar</code> or <code>spar</code> array was altered by mistake.
<code>stat= -3</code>	The routine stopped because the memory was insufficient to complete the computations.
<code>stat= -100</code>	The routine stopped because an error in the user's data was found or the data in the <code>dpar</code> , <code>spar</code> or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of the Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

free_Helmholtz_2D/free_Helmholtz_3D

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, int* stat);
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE* yhandle, int* ipar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<code>xhandle, yhandle</code>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structure <code>yhandle</code> is used only by <code>free_Helmholtz_3D</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

Output Parameters

<code>xhandle, yhandle</code>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Status of the routine call is written to <code>ipar[0]</code> .
<code>stat</code>	int*. Routine completion status, which is also written to <code>ipar[0]</code> .

Description

The `free_Helmholtz_2D-free_Helmholtz_3D` routine cleans the memory used by the `xhandle` and `yhandle` structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

PL Routines for the Spherical Solver

The section gives detailed description of spherical PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, periodic (having names ending in "p") and non-periodic (having names ending in "np"), are described together.

These PL routines also call the Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_sph_p/?_init_sph_np

Initializes basic data structures of the Fast periodic and non-periodic Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p(double* ap, double* at, double* bp, double* bt, int* np, int* nt,
double* q, int* ipar, double* dpar, int* stat);
void s_init_sph_p(float* ap, float* at, float* bp, float* bt, int* np, int* nt, float*
q, int* ipar, float* spar, int* stat);
void d_init_sph_np(double* ap, double* at, double* bp, double* bt, int* np, int* nt,
double* q, int* ipar, double* dpar, int* stat);
void s_init_sph_np(float* ap, float* at, float* bp, float* bt, int* np, int* nt, float*
q, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<code>ap</code>	<code>double* for d_init_sph_p/d_init_sph_np,</code> <code>float* for s_init_sph_p/s_init_sph_np.</code> <code>The coordinate (angle) of the leftmost boundary of the domain along φ-axis.</code>
<code>bp</code>	<code>double* for d_init_sph_p/d_init_sph_np,</code> <code>float* for s_init_sph_p/s_init_sph_np.</code> <code>The coordinate (angle) of the rightmost boundary of the domain along φ-axis.</code>
<code>at</code>	<code>double* for d_init_sph_p/d_init_sph_np,</code> <code>float* for s_init_sph_p/s_init_sph_np.</code> <code>The coordinate (angle) of the leftmost boundary of the domain along θ-axis.</code>
<code>bt</code>	<code>double* for d_init_sph_p/d_init_sph_np,</code> <code>float* for s_init_sph_p/s_init_sph_np.</code> <code>The coordinate (angle) of the rightmost boundary of the domain along θ-axis.</code>

<i>np</i>	int*. The number of mesh intervals along ϕ -axis. Must be even in the periodic case.
<i>nt</i>	int*. The number of mesh intervals along θ -axis.
<i>q</i>	double* for <i>d_init_sph_p/d_init_sph_np</i> , float* for <i>s_init_sph_p/s_init_sph_np</i> . The constant Helmholtz coefficient. Note that to solve Poisson problem, you should set the value of <i>q</i> to 0.

Output Parameters

<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The `?_init_sph_p/?_init_sph_np` routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

WARNING Data structures initialized and created by periodic/non-periodic flavors of the routine cannot be used by non-periodic/periodic flavors of any PL routines for Helmholtz Solver on a sphere, respectively.

You can skip calling this routine in your code. However, see [Caveat on Parameter Modifications](#) before doing so.

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of fatal error.

[?_commit_sph_p/?_commit_sph_np](#)

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s,
DFTI_DESCRIPTOR_HANDLE* handle_c, int* ipar, double* dpar, int* stat);

void s_commit_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, int* ipar, float* spar, int* stat);
```

```
void d_commit_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, double* dpar, int* stat);
void s_commit_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: mkl_poisson.f90
- C: mkl.h

Input Parameters

<i>f</i>	double* for <code>d_commit_sph_p/d_commit_sph_np</code> , float* for <code>s_commit_sph_p/s_commit_sph_np</code> . Contains the right-hand side of the problem packed in a single vector. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in <code>f[i+j*(np+1)]</code> . Note that the array <i>f</i> may be altered by the routine. Please save this vector in another memory location if you want to preserve it.
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>f</i>	Vector of the right-hand side of the problem. Possibly, altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms"). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> .
<i>stat</i>	int*. Routine completion status, which is also written to <code>ipar[0]</code> . The status should be 0 to proceed to other PL routines.

Description

The `?_commit_sph_p/?_commit_sph_np` routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle_s* and *handle_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the [Caveat on Parameter Modifications section](#). Unlike `?_init_sph_p/?_init_sph_np`, the routines `?_commit_sph_p/?_commit_sph_np` are mandatory, and you cannot skip calling them in your code. Values of `np` and `nt` are passed to each of the routines with the `ipar` array and defined in a previous call to the appropriate `?_init_sph_p/?_init_sph_np` routine.

Return Values

<code>stat= 1</code>	The routine completed without errors and produced some warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the user's data was found or the data in the <code>dpar</code> , <code>spar</code> or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

?_sph_p/?_sph_np

Computes the solution of a spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, int* ipar, double* dpar, int* stat);
void s_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, int* ipar, float* spar, int* stat);
void d_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, double* dpar, int* stat);
void s_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<code>f</code>	<code>double*</code> for <code>d_sph_p/d_sph_np</code> , <code>float*</code> for <code>s_sph_p/s_sph_np</code> . Contains the right-hand side of the problem packed in a single vector and modified by the appropriate <code>?_commit_sph_p/?_commit_sph_np</code> routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector is $(np+1) \times (nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$.
----------------	---

<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). <i>handle_s</i> and <i>handle_c</i> are used only in ?_sph_p and <i>handle</i> is used only in ?_sph_np.
<i>ipar</i>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<i>f</i>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	Data structures used by the Intel MKL FFT interface.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters .
<i>stat</i>	int*. Routine completion status, which is also written to <i>ipar[0]</i> . The status should be 0 to proceed to other PL routines.

Description

The sph_p-sph_np routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Library Implemented](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate ?_init_sph_p/?_init_sph_np routine.

Return Values

<i>stat</i> = 1	The routine completed without errors and produced some warnings.
<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -2	The routine stopped because division by zero occurred. It usually happens if the data in the <i>dpar</i> or <i>spar</i> array was altered by mistake.
<i>stat</i> = -3	The routine stopped because the memory was insufficient to complete the computations.
<i>stat</i> = -100	The routine stopped because an error in the user's data was found or the data in the <i>dpar</i> , <i>spar</i> or <i>ipar</i> array was altered by mistake.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.

<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c,
int* ipar, int* stat);
void free_sph_np(DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl.h`

Input Parameters

<code>handle_s, handle_c,</code> <code>handle</code>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structures <code>handle_s</code> and <code>handle_c</code> are used only in <code>free_sph_p</code> , and <code>handle</code> is used only in <code>free_sph_np</code> .
<code>ipar</code>	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

<code>handle_s, handle_c,</code> <code>handle</code>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Status of the routine call is written to <code>ipar[0]</code> .
<code>stat</code>	int*. Routine completion status, which is also written to <code>ipar[0]</code> .

Description

The `free_sph_p-free_sph_np` routine cleans the memory used by the `handle_s`, `handle_c` or `handle` structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of the Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

Common Parameters

This section provides description of array parameters *ipar*, *dpar* and *spar*, which hold PL routine options in both Cartesian and spherical cases.

NOTE Initial values are assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

ipar int array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in Table "Elements of the ipar Array":

Elements of the ipar Array

Index	Description
0	Contains status value of the last called PL routine. In general, it should be 0 to proceed with Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see Figure "Typical Order of Invoking PL Routines"). A non-zero value of <i>ipar[0]</i> with decimal representation
1	$\overline{abc} = 100a + 10b + c$ where each of <i>a</i> , <i>b</i> , and <i>c</i> is equal to 0 or 9, indicates that some parts of the Commit step should be omitted. <ul style="list-style-type: none"> If <i>c</i>=9, the routine omits checking of parameters and initialization of the data structures. If <i>b</i>=9, then in the Cartesian case, the routine omits the adjustment of the right-hand side vector <i>f</i> to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function <i>g</i>) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function <i>G</i>). In this case, the routine also omits the adjustment of the right-hand side vector <i>f</i> to the particular boundary functions. For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the <i>dpar/spar</i> array. If <i>a</i>=9, then the routine omits the normalization of the right-hand side vector <i>f</i>. In the 2D Cartesian case, it is the multiplication by <i>hy</i>², where <i>hy</i> is the mesh size in the <i>y</i> direction (for details, see Poisson Library Implemented). In the 3D (Cartesian) case, it is the multiplication by <i>hz</i>², where <i>hz</i> is the mesh size in the <i>z</i> direction. For the Helmholtz solver on a sphere, it is the multiplication by <i>hθ</i>², where <i>hθ</i> is the mesh size in the <i>θ</i> direction (for details, see Poisson Library Implemented). Using <i>ipar[0]</i> you can adjust the routine to your needs and gain efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious using this opportunity, because misunderstanding of the commit process may cause wrong results or program failure (see also Caveat on Parameter Modifications).

Contains error messaging options:

- ipar[1]=-1* indicates that all error messages will be printed to the file `MKL_Poisson_Library_log.txt` in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device.
- ipar[1]=0* indicates that no error messages will be printed.
- ipar[1]=1* is the default value. It indicates that all error messages will be printed to the preconnected default output device (usually, screen).

Index	Description
2	<p>In case of errors, the <i>stat</i> parameter will acquire a non-zero value regardless of the <i>ipar[1]</i> setting.</p>
2	<p>Contains warning messaging options:</p> <ul style="list-style-type: none"> • <i>ipar[2]</i>=-1 indicates that all warning messages will be printed to the file MKL_Poisson_Library_log.txt in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[2]</i>=0 indicates that no warning messages will be printed. • <i>ipar[2]</i>=1 is the default value. It indicates that all warning messages will be printed to the preconnected default output device (usually, screen).
3	<p>In case of warnings, the <i>stat</i> parameter will acquire a non-zero value regardless of the <i>ipar[2]</i> setting.</p>
3	<p>Contains the number of the combination of boundary conditions. In the Cartesian case, it corresponds to the value that the <i>BCtype</i> parameter holds:</p> <ul style="list-style-type: none"> • In the 2D case, <ul style="list-style-type: none"> 0 corresponds to 'DDDD' 1 corresponds to 'DDDN' ... 15 corresponds to 'NNNN' • In the 3D case, <ul style="list-style-type: none"> 0 corresponds to 'DDDDDD' 1 corresponds to 'DDDDDN' ... 63 corresponds to 'NNNNNN'.
4	<p>The Helmholtz solver on a sphere uses this parameter only in a periodic case. The <i>bp</i> and <i>bt</i> parameters of the ?_init_sph_p/?_init_sph_np routine, which initializes <i>ipar[3]</i>, determine its value:</p> <ul style="list-style-type: none"> • 0 corresponds to the problem without poles. • 1 corresponds to the problem on the entire sphere.
Parameters 4 through 9 are used only in Cartesian case.	
4	<p>Takes the value of 1 if <i>BCtype[0]</i>='N', 0 if <i>BCtype[0]</i>='D', and -1 otherwise.</p>
5	<p>Takes the value of 1 if <i>BCtype[1]</i>='N', 0 if <i>BCtype[1]</i>='D', and -1 otherwise.</p>
6	<p>Takes the value of 1 if <i>BCtype[2]</i>='N', 0 if <i>BCtype[2]</i>='D', and -1 otherwise.</p>
7	<p>Takes the value of 1 if <i>BCtype[3]</i>='N', 0 if <i>BCtype[3]</i>='D', and -1 otherwise.</p>
8	<p>Takes the value of 1 if <i>BCtype[4]</i>='N', 0 if <i>BCtype[4]</i>='D', and -1 otherwise. This parameter is used only in the 3D case.</p>
9	<p>Takes the value of 1 if <i>BCtype[5]</i>='N', 0 if <i>BCtype[5]</i>='D', and -1 otherwise. This parameter is used only in the 3D case.</p>
10	<p>Takes the value of</p> <ul style="list-style-type: none"> • <i>nx</i>, that is, the number of intervals along <i>x</i>-axis, in the Cartesian case. • <i>np</i>, that is, the number of intervals along <i>φ</i>-axis, in the spherical case.
11	<p>Takes the value of</p>

Index	Description			
	<ul style="list-style-type: none"> • ny, that is, the number of intervals along y-axis, in the Cartesian case • nt, that is, the number of intervals along θ-axis, in the spherical case. 			
12	Takes the value of nz , the number of intervals along z -axis. This parameter is used only in the 3D case (Cartesian).			
13	Takes the value of 6, which specifies the internal partitioning of the $dpar/spar$ array.			
14	Takes the value of $ipar[13]+ipar[10]+1$, which specifies the internal partitioning of the $dpar/spar$ array.			
Subsequent values of $ipar$ depend upon the dimension of the problem or upon whether the solver on a sphere is periodic.				
	2D case	3D case	Periodic case	Non-periodic case
15	Unused	Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the $dpar/spar$ array.		
16	Unused	Takes the value of $ipar[14]+ipar[11]+1$, which specifies the internal partitioning of the $dpar/spar$ array.		
17	Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[16]+1$, which specifies the internal partitioning of the $dpar/spar$ array.		
18	Takes the value of $ipar[14]+3*ipar[10]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[16]+3*ipar[10]/4+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.
19	Unused	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the $dpar/spar$ array.		Unused
20	Unused	Takes the value of $ipar[18]+3*ipar[11]/2+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Takes the value of $ipar[18]+3*ipar[10]/4+1$, which specifies the internal partitioning of the $dpar/spar$ array.	Unused
Subsequent values of $ipar$ are assigned regardless.				
21	Contains message style options: <ul style="list-style-type: none"> • $ipar[21]=0$ indicates that PL routines print all error and warning messages in Fortran-style notations. • $ipar[21]=1$ (default) indicates that PL routines print the messages in C-style notations. 			
22	Contains the number of threads to be used for computations in a multithreaded environment. The default value is 1 in the serial mode, and the result returned by the mkl_get_max_threads function otherwise.			

Index	Description
23 through 39	Unused in the current implementation of the Poisson Library.
40 through 59	Contain the first twenty elements of the <i>ipar</i> array of the first Trigonometric Transform that the Solver uses. (For details, see Common Parameters in the "Trigonometric Transform Routines" chapter.)
60 through 79	Contain the first twenty elements of the <i>ipar</i> array of the second Trigonometric Transform that the 3D and periodic solvers use. (For details, see Common Parameters in the "Trigonometric Transform Routines" chapter.)

NOTE You may declare the *ipar* array in your code as `int ipar[80]`. However, for compatibility with later versions of Intel MKL Poisson Library, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays `dpar` and `spar` are the same except in the data precision:

dpar Holds data needed for double-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, double array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case; initialized in the `d_init_Helmholtz_2D/` `d_init_Helmholtz_3D` and `d_commit_Helmholtz_2D/` `d_commit_Helmholtz_3D` routines.
- For the spherical solver, double array of size $5*np/2+nt+10$; initialized in the `d_init_sph_p/d_init_sph_np` and `d_commit_sph_p/` `d_commit_sph_np` routines.

spar Holds data needed for single-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, float array of size $5*nx/2+7$ in the 2D case or $5*(nx+ny)/2+9$ in the 3D case; initialized in the `s_init_Helmholtz_2D/` `s_init_Helmholtz_3D` and `s_commit_Helmholtz_2D/` `s_commit_Helmholtz_3D` routines.
- For the spherical solver, float array of size $5*np/2+nt+10$; initialized in the `s_init_sph_p/s_init_sph_np` and `s_commit_sph_p/s_commit_sph_np` routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table "Elements of the *dpar* and *spar* Arrays":

Elements of the dpar and spar Arrays

Index	Description
0	<p>In the Cartesian case, contains the length of the interval along x-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_x in the x direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p> <p>In the spherical case, contains the length of the interval along ϕ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_ϕ in the ϕ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.</p>
1	<p>In the Cartesian case, contains the length of the interval along y-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_y in the y direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.</p>

Index	Description
	In the spherical case, contains the length of the interval along θ -axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_θ in the θ direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
2	In the Cartesian case, contains the length of the interval along z -axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_z in the z direction (for details, see Poisson Library Implemented) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the Cartesian solver, this parameter is used only in the 3D case.
	In the spherical solver, contains the coordinate of the leftmost boundary along θ -axis after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine.
3	Contains the value of the coefficient q after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.
4	Contains the tolerance parameter after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine. <ul data-bbox="414 789 1462 1199" style="list-style-type: none"> <li data-bbox="414 789 1462 1043">In the Cartesian case, this value is used only for the pure Neumann boundary conditions (<code>BCtype="NNNN"</code> in the 2D case; <code>BCtype="NNNNNN"</code> in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient q is zero. Poisson Library verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, Poisson Library computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the <code>?_Helmholtz_2D/?_Helmholtz_3D</code> routine informs the user that the solution may not exist in a classical sense (up to rounding errors). <li data-bbox="414 1056 1462 1199">In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the above described Cartesian case with pure Neumann boundary conditions. So, here Poisson Library computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors.
	The default value for this parameter is $1.0E-10$ in case of double-precision computations or $1.0E-4$ in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.
<i>ipar[13]-1</i> through <i>ipar[14]-1</i>	In the Cartesian case, contain the spectrum of the 1D problem along x -axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine.
<i>ipar[15]-1</i> through <i>ipar[16]-1</i>	In the spherical case, contains the spectrum of the 1D problem along ϕ -axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
	In the Cartesian case, contain the spectrum of the 1D problem along y -axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. These elements are used only in the 3D case.
	In the spherical case, contains the spherical weights after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
	Take the values of the (staggered) sine/cosine in the mesh points:
	<ul data-bbox="414 1731 1445 1839" style="list-style-type: none"> <li data-bbox="414 1731 1171 1790">along x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian solver <li data-bbox="414 1795 1445 1839">along ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine for a spherical solver.

Index	Description
<i>ipar[19]-1</i> through <i>ipar[20]-1</i>	<p>Take the values of the (staggered) sine/cosine in the mesh points:</p> <ul style="list-style-type: none"> • along y-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian 3D solver • along ϕ-axis after a call to the <code>?_commit_sph_p</code> routine for a spherical periodic solver. <p>These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.</p>

NOTE You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the PL interface enables you to skip calling the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE To supply correct and consistent parameters to PL routines, you should have considerable experience in using the PL interface and good understanding of the solution process as well as elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail in tuning parameters for the Fast Helmholtz Solver. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL PL interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the PL language-specific header files to include in their code. Currently, the following header files are available:

- `mkl_poisson.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_poisson.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

Use of the Intel MKL PL software without including one of the above header files is not supported.

The include files define function prototypes for appropriate languages.

C-specific Header File

The C-specific header file defines the following function prototypes for the Cartesian solver:

```
void d_init_Helmholtz_2D(double*, double*, double*, double*, int*, int*, char*, double*, int*, double*, int*);  
void d_commit_Helmholtz_2D(double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
void d_Helmholtz_2D(double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
  
void s_init_Helmholtz_2D(float*, float*, float*, float*, int*, int*, char*, float*, int*, float*, int*);  
void s_commit_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
void s_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
  
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE*, int*, int*);  
  
void d_init_Helmholtz_3D(double*, double*, double*, double*, double*, double*, int*, int*, int*, char*, double*, int*, double*, int*);  
void d_commit_Helmholtz_3D(double*, double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
void d_Helmholtz_3D(double*, double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
  
void s_init_Helmholtz_3D(float*, float*, float*, float*, float*, float*, int*, int*, int*, char*, float*, int*, float*, int*);  
void s_commit_Helmholtz_3D(float*, float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
void s_Helmholtz_3D(float*, float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
  
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

The C-specific header file defines the following function prototypes for the spherical solver:

```
void d_init_sph_p(double*, double*, double*, double*, int*, int*, double*, int*, double*, int*);  
void d_commit_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
void d_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
void s_init_sph_p(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);  
void s_commit_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
void s_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
void free_sph_p(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);  
  
void d_init_sph_np(double*, double*, double*, double*, int*, int*, double*, int*, double*, int*);  
void d_commit_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
void d_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);  
void s_init_sph_np(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);  
void s_commit_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
void s_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);  
void free_sph_np(DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes for the Cartesian solver:

```

Fortran 90 specifics of the PL routines usage are similar for all Intel MKL PDE support tools and described in the [Calling PDE Support Routines from Fortran 90](#) section.

Calling PDE Support Routines from Fortran 90

The calling interface for all the Intel MKL TT and PL routines is designed to be easily used in C. However, you can invoke each TT or PL routine directly from Fortran 90 if you are familiar with the inter-language calling conventions of your platform.

The TT or PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of the Intel MKL FFT interface.

The inter-language calling conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from C to Fortran 90 and how C external names are decorated on the platform.

To promote portability and relieve a user of dealing with the calling conventions specifics, Fortran 90 header file `mkl_trig_transforms.f90` for TT routines and `mkl_poisson.f90` for PL routines, used together with `mkl_dfti.f90`, declare a set of macros and introduce type definitions intended to hide the inter-language calling conventions and provide an interface to the routines that looks natural in Fortran 90.

For example, consider a hypothetical library routine, `foo`, which takes a double-precision vector of length `n`. C users access such a function as follows:

```
int n;
double *x;
...
foo(x, &n);
```

As noted above, to invoke `foo`, Fortran 90 users would need to know what Fortran 90 data types correspond to C types `int` and `double` (or `float` in case of single-precision), what argument-passing mechanism the C compiler uses and what, if any, name decoration is performed by the C compiler when generating the external symbol `foo`. However, with the Fortran 90 header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` included, the invocation of `foo` within a Fortran 90 program will look as follows:

- For TT interface,

```
use mkl_dfti
use mkl_trig_transforms
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

- For PL interface,

```
use mkl_dfti
use mkl_poisson
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
...
CALL FOO(x,n)
```

Note that in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` provide a definition for the subroutine `FOO`. To ease the use of PL or TT routines in Fortran 90, the general approach of providing Fortran 90 definitions of names is used throughout the libraries. Specifically, if a name from a PL or TT interface is documented as having the C-specific name `foo`, then the Fortran 90 header files provide an appropriate Fortran 90 language type definition `FOO`.

One of the key differences between Fortran 90 and C is the language argument-passing mechanism: C programs use pass-by-value semantics and Fortran 90 programs use pass-by-reference semantics. The Fortran 90 headers ensure proper treatment of this difference. In particular, in the above example, the header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` hide the difference by defining a macro `FOO` that takes the address of the appropriate arguments.

Nonlinear Optimization Problem Solvers

14

Intel® Math Kernel Library (Intel® MKL) provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. The solver routines are grouped according to their purpose as follows:

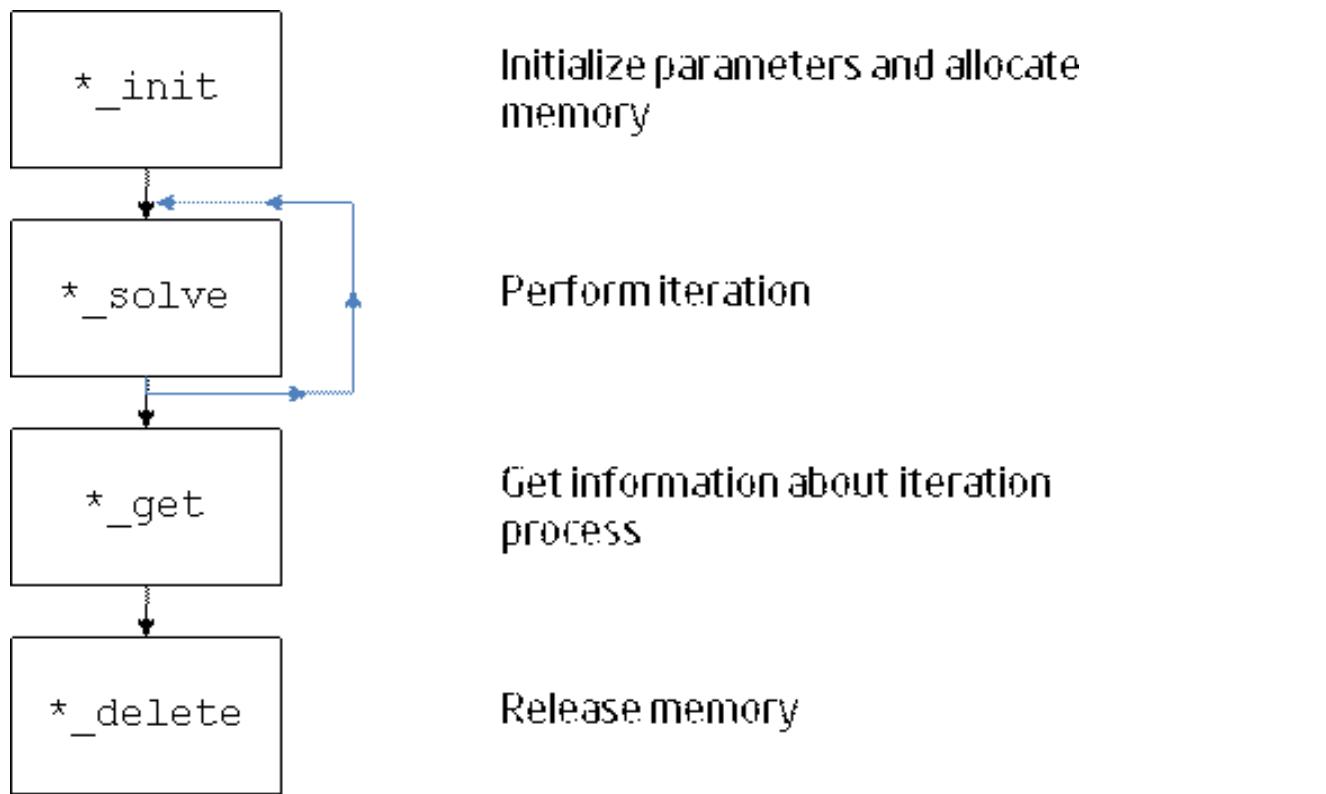

- Nonlinear Least Squares Problem without Constraints
- Nonlinear Least Squares Problem with Linear (Boundary) Constraints
- Jacobian Matrix Calculation Routines

For more information on the key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [Conn00].

Organization and Implementation

The Intel MKL solver routines for nonlinear least squares problems use reverse communication interfaces (RCI). That means you need to provide the solver with information required for the iteration process, for example, the corresponding Jacobian matrix, or values of the objective function. RCI removes the dependency of the solver on specific implementation of the operations. However, it does require that you organize a computational loop.

Typical order for invoking RCI solver routines

The nonlinear least squares problem solver routines, or Trust-Region (TR) solvers, are implemented with the OpenMP* support. You can manage the threads using [threading control functions](#).

Memory Allocation and Handles

To make the TR solver routines easy to use, you are not required to allocate temporary working storage. The solver allocates any required memory. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*. Each TR solver routine creates, uses, or deletes a handle. To declare a handle, include `mkl_rci.h` or `mkl_rci.fi`.

For a C and C++ program, declare a handle as one of the following:

```
#include "mkl_rci.h"
_TRNSP_HANDLE_t handle;
```

or

```
_TRNSPBC_HANDLE_t handle;
```

The first declaration is used for nonlinear least squares problems without boundary constraints, and the second is used for nonlinear least squares problems with boundary constraints.

For a Fortran program using compilers that support eight byte integers, declare a handle as:

```
INCLUDE "mkl_rci.fi"
INTEGER*8 handle
```

Routine Naming Conventions

The TR routine names have the following structure:

```
<character><name>_<action>( )
```

where

- `<character>` indicates the data type:

s	real, single precision
d	real, double precision

- `<name>` indicates the task type:

trnlsp	nonlinear least squares problem without constraints
trnlspbc	nonlinear least squares problem with boundary constraints
jacobi	computation of the Jacobian matrix using central differences

- `<action>` indicates an action on the task:

init	initializes the solver
check	checks correctness of the input parameters
solve	solves the problem
get	retrieves the number of iterations, the stop criterion, the initial residual, and the final residual
delete	releases the allocated data

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n,$$

where

$F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$ is a twice differentiable function in \mathbb{R}^n .

Solving a nonlinear least squares problem means searching for the best approximation to the vector y with the model function $f_i(x)$ and nonlinear variables x . The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the minimum.

See usage examples in FORTRAN and C in the `examples\solver\source` folder of your Intel MKL directory (`ex_nlsqp_f.f` and `ex_nlsqp_c.c`, respectively).

RCI TR Routines

Routine Name	Operation
?trnlsp_init	Initializes the solver.
?trnlsp_check	Checks correctness of the input parameters.
?trnlsp_solve	Solves a nonlinear least squares problem using the Trust-Region algorithm.
?trnlsp_get	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
?trnlsp_delete	Releases allocated data.

?trnlsp_init

Initializes the solver of a nonlinear least squares problem.

Syntax

Fortran:

```
res = strnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
res = dtrnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
```

C:

```
res = strnlsp_init(&handle, &n, &m, x, eps, &iter1, &iter2, &rs);
res = dtrnlsp_init(&handle, &n, &m, x, eps, &iter1, &iter2, &rs);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?trnlsp_init` routine initializes the solver.

After initialization, all subsequent invocations of the `?trnlsp_solve` routine should use the values of the handle returned by `?trnlsp_init`.

The `eps` array contains the stopping criteria:

eps Value	Description
1	$\Delta < \text{eps}(1)$
2	$\ F(x)\ _2 < \text{eps}(2)$
3	The Jacobian matrix is singular. $\ J(x)_{(1:m,j)}\ _2 < \text{eps}(3), j = 1, \dots, n$

eps Value	Description
4	$\ s\ _2 < \text{eps}(4)$
5	$\ F(x)\ _2 - \ F(x) - J(x)s\ _2 < \text{eps}(5)$
6	The trial step precision. If $\text{eps}(6) = 0$, then the trial step meets the required precision ($\leq 1.0D-10$).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>n</i>	INTEGER. Length of x .
<i>m</i>	INTEGER. Length of $F(x)$.
<i>x</i>	REAL for strnlsp_init DOUBLE PRECISION for dtrnlsp_init Array of size <i>n</i> . Initial guess.
<i>eps</i>	REAL for strnlsp_init DOUBLE PRECISION for dtrnlsp_init Array of size 6; contains stopping criteria. See the values in the Description section.
<i>iter1</i>	INTEGER. Specifies the maximum number of iterations.
<i>iter2</i>	INTEGER. Specifies the maximum number of iterations of trial step calculation.
<i>rs</i>	REAL for strnlsp_init DOUBLE PRECISION for dtrnlsp_init Definition of initial size of the trust region (boundary of the trial step). The minimum value is 0.1, and the maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. The default value is 100.0.

Output Parameters

<i>handle</i>	Type <code>_TRNSP_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>res</i>	INTEGER. Indicates task completion status. <ul style="list-style-type: none"> • <i>res</i> = <code>TR_SUCCESS</code> - the routine completed the task normally. • <i>res</i> = <code>TR_INVALID_OPTION</code> - there was an error in the input parameters. • <i>res</i> = <code>TR_OUT_OF_MEMORY</code> - there was a memory error. <code>TR_SUCCESS</code> , <code>TR_INVALID_OPTION</code> , and <code>TR_OUT_OF_MEMORY</code> are defined in <code>mkl_rci.fi</code> (Fortran) and <code>mkl_rci.h</code> (C) include files.

See Also

[?trnlsp_solve](#)

?trnlsp_check

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, and stopping criteria.

Syntax

Fortran:

```
res = strnlsp_check(handle, n, m, fjac, fvec, eps, info)
res = dtrnlsp_check(handle, n, m, fjac, fvec, eps, info)
```

C:

```
res = strnlsp_check(&handle, &n, &m, fjac, fvec, eps, info);
res = dtrnlsp_check(&handle, &n, &m, fjac, fvec, eps, info);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?trnlsp_check routine checks the arrays passed into the solver as input parameters. If an array contains any INF or NaN values, the routine sets the flag in output array *info* (see the description of the values returned in the Output Parameters section for the *info* array).

Input Parameters

<i>handle</i>	Type _TRNSPBC_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.
<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F(x)</i> .
<i>fjac</i>	REAL for strnlsp_check DOUBLE PRECISION for dtrnlsp_check Array of size <i>m</i> by <i>n</i> . Contains the Jacobian matrix of the function.
<i>fvec</i>	REAL for strnlsp_check DOUBLE PRECISION for dtrnlsp_check Array of size <i>m</i> . Contains the function values at <i>x</i> , where <i>fvec(i) = (y_i - f_i(x))</i> .
<i>eps</i>	REAL for strnlsp_check DOUBLE PRECISION for dtrnlsp_check Array of size 6; contains stopping criteria. See the values in the Description section of the ?trnlsp_init.

Output Parameters

<i>info</i>	INTEGER Array of size 6. Results of input parameter checking:
-------------	---

Parameter		Used for	Value	Description
C Language	Fortran Language			
<i>info</i> (0)	<i>info</i> (1)	Flags for handle	0	The handle is valid.
			1	The handle is not allocated.
<i>info</i> (1)	<i>info</i> (2)	Flags for <i>fjac</i>	0	The <i>fjac</i> array is valid.
			1	The <i>fjac</i> array is not allocated
<i>info</i> (2)	<i>info</i> (3)	Flags for <i>fvec</i>	2	The <i>fjac</i> array contains NaN.
			3	The <i>fjac</i> array contains Inf.
			0	The <i>fvec</i> array is valid.
<i>info</i> (3)	<i>info</i> (4)	Flags for <i>eps</i>	1	The <i>fvec</i> array is not allocated
			2	The <i>fvec</i> array contains NaN.
			3	The <i>fvec</i> array contains Inf.
<i>info</i> (4)		Flags for <i>eps</i>	0	The <i>eps</i> array is valid.
			1	The <i>eps</i> array is not allocated
			2	The <i>eps</i> array contains NaN.
			3	The <i>eps</i> array contains Inf.
			4	The <i>eps</i> array contains a value less than or equal to zero.

res

INTEGER. Information about completion of the task.

res = TR_SUCCESS - the routine completed the task normally.

TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?trnlsp_solve

Solves a nonlinear least squares problem using the TR algorithm.

Syntax

Fortran:

```
res = strnlsp_solve(handle, fvec, fjac, RCI_Request)
res = dtrnlsp_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = strnlsp_solve(&handle, fvec, fjac, &RCI_Request);
res = dtrnlsp_solve(&handle, fvec, fjac, &RCI_Request);
```

Include Files

- Fortran: mkl_rci.fi

- C: mkl_rci.h

Description

The ?trnlsp_solve routine uses the TR algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n,$$

where

- $F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$
- $m \geq n$

From a current point $x_{current}$, the algorithm uses the trust-region approach:

$$\min_{x \in \mathbb{R}^n} \|F(x_{current}) + J(x_{current})(x_{new} - x_{current})\|_2^2 \quad \text{subject to } \|x_{new} - x_{current}\| \leq \Delta_{current}$$

to get $x_{new} = x_{current} + s$ that satisfies

$$\min_{x \in \mathbb{R}^n} \|J^T(x)J(x)s + J^T F(x)\|_2^2$$

where

- $J(x)$ is the Jacobian matrix
- s is the trial step
- $\|s\|_2 \leq \Delta_{current}$

The RCI_Request parameter provides additional information:

<i>RCI_Request</i>	<i>Value</i>	<i>Description</i>
2		Request to calculate the Jacobian matrix and put the result into <i>fjac</i>
1		Request to recalculate the function at vector <i>x</i> and put the result into <i>fvec</i>
0		One successful iteration step on the current trust-region radius (that does not mean that the value of <i>x</i> has changed)
-1		The algorithm has exceeded the maximum number of iterations
-2		$\Delta < \text{eps}(1)$
-3		$\ F(x)\ _2 < \text{eps}(2)$
-4		The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m,j)}\ _2 < \text{eps}(3), j = 1, \dots, n$
-5		$\ s\ _2 < \text{eps}(4)$
-6		$\ F(x)\ _2 - \ F(x) - \mathcal{J}(x)s\ _2 < \text{eps}(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>handle</i>	Type <code>_TRNSP_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	<code>REAL</code> for <code>strnlsp_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlsp_solve</code> Array of size m . Contains the function values at x , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	<code>REAL</code> for <code>strnlsp_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlsp_solve</code> Array of size (m, n) . Contains the Jacobian matrix of the function.

Output Parameters

<i>fvec</i>	<code>REAL</code> for <code>strnlsp_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlsp_solve</code> Array of size m . Updated function evaluated at x .
<i>RCI_Request</i>	<code>INTEGER</code> . Informs about the task stage. See the Description section for the parameter values and their meaning.
<i>res</i>	<code>INTEGER</code> . Indicates the task completion. $res = TR_SUCCESS$ - the routine completed the task normally. <code>TR_SUCCESS</code> is defined in the <code>mkl_rci.h</code> and <code>mkl_rci.fi</code> include files.

?trnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = strnlsp_get(handle, iter, st_cr, r1, r2)
```

```
res = dtrnlsp_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = strnlsp_get(&handle, &iter, &st_cr, &r1, &r2);
```

```
res = dtrnlsp_get(&handle, &iter, &st_cr, &r1, &r2);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The initial residual is the value of the functional $(||y - f(x)||)$ of the initial x values provided by the user.

The final residual is the value of the functional $(||y - f(x)||)$ of the final x resulting from the algorithm operation.

The `st_cr` parameter contains the stop criterion:

<code>st_cr</code> Value	Description
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < \text{eps}(1)$
3	$ F(x) _2 < \text{eps}(2)$
4	The Jacobian matrix is singular. $ \mathcal{J}(x)_{(1:m, j)} _2 < \text{eps}(3), j = 1, \dots, n$
5	$ s _2 < \text{eps}(4)$
6	$ F(x) _2 - F(x) - \mathcal{J}(x)s _2 < \text{eps}(5)$

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

`handle` Type `_TRNLP_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

<code>iter</code>	INTEGER. Contains the current number of iterations.
<code>st_cr</code>	INTEGER. Contains the stop criterion. See the Description section for the parameter values and their meanings.
<code>r1</code>	REAL for <code>strnlsp_get</code> DOUBLE PRECISION for <code>dtrnlsp_get</code> Contains the residual, $(y - f(x))$ given the initial x .
<code>r2</code>	REAL for <code>strnlsp_get</code> DOUBLE PRECISION for <code>dtrnlsp_get</code> Contains the final residual, that is, the value of the functional $(y - f(x))$ of the final x resulting from the algorithm operation.
<code>res</code>	INTEGER. Indicates the task completion. <code>res = TR_SUCCESS</code> - the routine completed the task normally. <code>TR_SUCCESS</code> is defined in the <code>mkl_rci.h</code> and <code>mkl_rci.fi</code> include files.

?trnlsp_delete

Releases allocated data.

Syntax

Fortran:

```
res = strnlsp_delete(handle)
res = dtrnlsp_delete(handle)
```

C:

```
res = strnlsp_delete(&handle);
res = dtrnlsp_delete(&handle);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?trnlsp_delete routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function `mkl_free_buffers`.

Input Parameters

`handle` Type `_TRNSP_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

`res` INTEGER. Indicates the task completion.
`res = TR_SUCCESS` means the routine completed the task normally.
`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints is very similar to the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, n, \quad l, u \in R^n.$$

See usage examples in FORTRAN and C in the `examples\solver\source` folder of your Intel MKL directory (`ex_nlsqp_bc_f.f` and `ex_nlsqp_bc_c.c`, respectively).

RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
?trnlspbc_init	Initializes the solver.
?trnlspbc_check	Checks correctness of the input parameters.
?trnlspbc_solve	Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.
?trnlspbc_get	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
?trnlspbc_delete	Releases allocated data.

?trnlspbc_init

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

Fortran:

```
res = strnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
res = dtrnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
```

C:

```
res = strnlspbc_init(&handle, &n, &m, x, LW, UP, eps, &iter1, &iter2, &rs);
res = dtrnlspbc_init(&handle, &n, &m, x, LW, UP, eps, &iter1, &iter2, &rs);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?trnlspbc_init routine initializes the solver.

After initialization all subsequent invocations of the ?trnlspbc_solve routine should use the values of the handle returned by ?trnlspbc_init.

The *eps* array contains the stopping criteria:

eps Value	Description
1	$\Delta < \text{eps}(1)$
2	$\ F(x)\ _2 < \text{eps}(2)$
3	The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m,j)}\ _2 < \text{eps}(3), j = 1, \dots, n$
4	$\ s\ _2 < \text{eps}(4)$
5	$\ F(x)\ _2 - \ F(x) - \mathcal{J}(x)s\ _2 < \text{eps}(5)$
6	The trial step precision. If $\text{eps}(6) = 0$, then the trial step meets the required precision ($\leq 1.0D-10$).

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of $F(x)$.

<i>x</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init Array of size <i>n</i> . Initial guess.
<i>LW</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init Array of size <i>n</i> . Contains low bounds for <i>x</i> ($lw_i < x_i$).
<i>UP</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init Array of size <i>n</i> . Contains upper bounds for <i>x</i> ($up_i > x_i$).
<i>eps</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init Array of size 6; contains stopping criteria. See the values in the Description section.
<i>iter1</i>	INTEGER. Specifies the maximum number of iterations.
<i>iter2</i>	INTEGER. Specifies the maximum number of iterations of trial step calculation.
<i>rs</i>	REAL for strnlspbc_init DOUBLE PRECISION for dtrnlspbc_init Definition of initial size of the trust region (boundary of the trial step). The minimum value is 0.1, and the maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. The default value is 100.0.

Output Parameters

<i>handle</i>	Type _TRNSPBC_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.
<i>res</i>	INTEGER. Informs about the task completion. <ul style="list-style-type: none"> • <i>res</i> = TR_SUCCESS - the routine completed the task normally. • <i>res</i> = TR_INVALID_OPTION - there was an error in the input parameters. • <i>res</i> = TR_OUT_OF_MEMORY - there was a memory error. TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

?trnlspbc_check

Checks the correctness of *handle* and arrays containing Jacobian matrix, objective function, lower and upper bounds, and stopping criteria.

Syntax

Fortran:

```
res = strnlspbc_check(handle, n, m, fjac, fvec, LW, UP, eps, info)
res = dtrnlspbc_check(handle, n, m, fjac, fvec, LW, UP, eps, info)
```

C:

```
res = strnlspbc_check(&handle, &n, &m, fjac, fvec, LW, UP, eps, info);
res = dtrnlspbc_check(&handle, &n, &m, fjac, fvec, LW, UP, eps, info);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The `?trnlspbc_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NAN` values, the routine sets the flag in output array `info` (see the description of the values returned in the Output Parameters section for the `info` array).

Input Parameters

<code>handle</code>	Type <code>_TRNSPBC_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<code>n</code>	<code>INTEGER</code> . Length of <code>x</code> .
<code>m</code>	<code>INTEGER</code> . Length of <code>F(x)</code> .
<code>fjac</code>	<code>REAL</code> for <code>strnlspbc_check</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_check</code> Array of size <code>m</code> by <code>n</code> . Contains the Jacobian matrix of the function.
<code>fvec</code>	<code>REAL</code> for <code>strnlspbc_check</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_check</code> Array of size <code>m</code> . Contains the function values at <code>x</code> , where <code>fvec(i) = (y_i - f_i(x))</code> .
<code>LW</code>	<code>REAL</code> for <code>strnlspbc_check</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_check</code> Array of size <code>n</code> . Contains low bounds for <code>x</code> ($lw_i < x_i$).
<code>UP</code>	<code>REAL</code> for <code>strnlspbc_check</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_check</code> Array of size <code>n</code> . Contains upper bounds for <code>x</code> ($up_i > x_i$).
<code>eps</code>	<code>REAL</code> for <code>strnlspbc_check</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_check</code> Array of size 6; contains stopping criteria. See the values in the Description section of the <code>?trnlspbc_init</code> .

Output Parameters

<code>info</code>	<code>INTEGER</code> Array of size 6. Results of input parameter checking:
-------------------	--

Parameter	Used for	Value	Description
C Language	Fortran Language		
<code>info(0)</code>	<code>info(1)</code>	Flags for handle	0 The handle is valid. 1 The handle is not allocated.
<code>info(1)</code>	<code>info(2)</code>	Flags for <code>fjac</code>	0 The <code>fjac</code> array is valid. 1 The <code>fjac</code> array is not allocated 2 The <code>fjac</code> array contains NaN.

Parameter		Used for	Value	Description
C Language	Fortran Language			
			3	The <i>fjac</i> array contains Inf.
<i>info</i> (2)	<i>info</i> (3)	Flags for <i>fvec</i>	0	The <i>fvec</i> array is valid.
			1	The <i>fvec</i> array is not allocated
			2	The <i>fvec</i> array contains NaN.
			3	The <i>fvec</i> array contains Inf.
<i>info</i> (3)	<i>info</i> (4)	Flags for <i>LW</i>	0	The <i>LW</i> array is valid.
			1	The <i>LW</i> array is not allocated
			2	The <i>LW</i> array contains NaN.
			3	The <i>LW</i> array contains Inf.
			4	The lower bound is greater than the upper bound.
<i>info</i> (4)	<i>info</i> (5)	Flags for <i>up</i>	0	The <i>up</i> array is valid.
			1	The <i>up</i> array is not allocated
			2	The <i>up</i> array contains NaN.
			3	The <i>up</i> array contains Inf.
			4	The upper bound is less than the lower bound.
<i>info</i> (5)	<i>info</i> (6)	Flags for <i>eps</i>	0	The <i>eps</i> array is valid.
			1	The <i>eps</i> array is not allocated
			2	The <i>eps</i> array contains NaN.
			3	The <i>eps</i> array contains Inf.
			4	The <i>eps</i> array contains a value less than or equal to zero.

res

INTEGER. Information about completion of the task.

res = TR_SUCCESS - the routine completed the task normally.

TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?trnlspbc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

Fortran:

```
res = strnlspbc_solve(handle, fvec, fjac, RCI_Request)
res = dtrnlspbc_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = strnlspbc_solve(&handle, fvec, fjac, &RCI_Request);
res = dtrnlspbc_solve(&handle, fvec, fjac, &RCI_Request);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?trnlspbc_solve routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, \quad y \in \mathbb{R}^m, \quad x \in \mathbb{R}^n, \quad f: \mathbb{R}^n \rightarrow \mathbb{R}^m, \quad m \geq n$$

where

$$l_i \leq x_i \leq u_i \\ i = 1, \dots, n.$$

The *RCI_Request* parameter provides additional information:

<i>RCI_Request</i>	Value	Description
2		Request to calculate the Jacobian matrix and put the result into <i>fjac</i>
1		Request to recalculate the function at vector <i>x</i> and put the result into <i>fvec</i>
0		One successful iteration step on the current trust-region radius (that does not mean that the value of <i>x</i> has changed)
-1		The algorithm has exceeded the maximum number of iterations
-2		$\Delta < \text{eps}(1)$
-3		$\ F(x)\ _2 < \text{eps}(2)$
-4		The Jacobian matrix is singular. $\ \mathcal{J}(x)_{(1:m, j)}\ _2 < \text{eps}(3), \quad j = 1, \dots, n$
-5		$\ s\ _2 < \text{eps}(4)$
-6		$\ F(x)\ _2 - \ F(x) - \mathcal{J}(x)s\ _2 < \text{eps}(5)$

Note:

- $\mathcal{J}(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.

- s is the trial step.

Input Parameters

<i>handle</i>	Type <code>_TRNSPBC_HANDLE_t</code> in C/C++ and <code>INTEGER*8</code> in FORTRAN.
<i>fvec</i>	<code>REAL</code> for <code>strnlspbc_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_solve</code> Array of size m . Contains the function values at x , where $fvec(i) = (y_i - f_i(x))$.
<i>fjac</i>	<code>REAL</code> for <code>strnlspbc_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_solve</code> Array of size m by n . Contains the Jacobian matrix of the function.

Output Parameters

<i>fvec</i>	<code>REAL</code> for <code>strnlspbc_solve</code> <code>DOUBLE PRECISION</code> for <code>dtrnlspbc_solve</code> Array of size m . Updated function evaluated at x .
<i>RCI_Request</i>	<code>INTEGER</code> . Informs about the task stage. See the Description section for the parameter values and their meaning.
<i>res</i>	<code>INTEGER</code> . Informs about the task completion. $res = \text{TR_SUCCESS}$ means the routine completed the task normally. <code>TR_SUCCESS</code> is defined in the <code>mkl_rci.h</code> and <code>mkl_rci.fi</code> include files.

?trnlspbc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = strnlspbc_get(handle, iter, st_cr, r1, r2)
res = dtrnlspbc_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = strnlspbc_get(&handle, &iter, &st_cr, &r1, &r2);
res = dtrnlspbc_get(&handle, &iter, &st_cr, &r1, &r2);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The `st_cr` parameter contains the stop criterion:

<code>st_cr</code> Value	Description
1	The algorithm has exceeded the maximum number of iterations

st_cr Value	Description
2	$\Delta < \text{eps}(1)$
3	$\ F(x) \ _2 < \text{eps}(2)$
4	The Jacobian matrix is singular. $\ J(x)_{(1:m,j)} \ _2 < \text{eps}(3), j = 1, \dots, n$
5	$\ s \ _2 < \text{eps}(4)$
6	$\ F(x) \ _2 - \ F(x) - J(x)s \ _2 < \text{eps}(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle Type `_TRNLPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

iter INTEGER. Contains the current number of iterations.

st_cr INTEGER. Contains the stop criterion.

See the Description section for the parameter values and their meanings.

r1 REAL for `strnlspbc_get`
DOUBLE PRECISION for `dtrnlspbc_get`
Contains the residual, $(\| y - f(x) \|)$ given the initial x .

r2 REAL for `strnlspbc_get`
DOUBLE PRECISION for `dtrnlspbc_get`
Contains the final residual, that is, the value of the function $(\| y - f(x) \|)$ of the final x resulting from the algorithm operation.

res INTEGER. Informs about the task completion.
res = `TR_SUCCESS` - the routine completed the task normally.
`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?trnlspbc_delete

Releases allocated data.

Syntax

Fortran:

```
res = strnlspbc_delete(handle)
res = dtrnlspbc_delete(handle)
```

C:

```
res = strnlspbc_delete(&handle);
res = dtrnlspbc_delete(&handle);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?trnlspbc_delete routine releases all memory allocated for the handle.

NOTE This routine flags memory as not used, but to actually release all memory you must call the support function [mkl_free_buffers](#).

Input Parameters

handle Type `_TRNSPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res INTEGER. Informs about the task completion.
`res = TR_SUCCESS` means the routine completed the task normally.
`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

Jacobian Matrix Calculation Routines

This section describes routines that compute the Jacobian matrix using the central difference algorithm. Jacobian matrix calculation is required to solve a nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobian matrix have the "Black-Box" interfaces, where you pass the objective function via parameters. Your objective function must have a fixed interface.

Jacobian Matrix Calculation Routines

Routine Name	Operation
?jacobi_init	Initializes the solver.
?jacobi_solve	Computes the Jacobian matrix of the function on the basis of RCI using the central difference algorithm.
?jacobi_delete	Removes data.
?jacobi	Computes the Jacobian matrix of the <code>fcn</code> function using the central difference algorithm.
?jacobix	Presents an alternative interface for the ?jacobi function enabling you to pass additional data into the objective function.

?jacobi_init

Initializes the solver for Jacobian calculations.

Syntax

Fortran:

```
res = sjacobi_init(handle, n, m, x, fjac, eps)
res = djacobi_init(handle, n, m, x, fjac, eps)
```

C:

```
res = sjacobi_init(&handle, &n, &m, x, fjac, &eps);
res = djacobi_init(&handle, &n, &m, x, fjac, &eps);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine initializes the solver.

Input Parameters

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Array of size <i>n</i> . Vector, at which the function is evaluated.
<i>eps</i>	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Precision of the Jacobian matrix calculation.
<i>fjac</i>	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Array of size (<i>m,n</i>). Contains the Jacobian matrix of the function.

Output Parameters

<i>handle</i>	Data object of the <i>_JACOBIMATRIX_HANDLE_t</i> type in C/C++ and <i>INTEGER*8</i> in FORTRAN.
<i>res</i>	INTEGER. Indicates task completion status. <ul style="list-style-type: none"> • <i>res</i> = <i>TR_SUCCESS</i> - the routine completed the task normally. • <i>res</i> = <i>TR_INVALID_OPTION</i> - there was an error in the input parameters. • <i>res</i> = <i>TR_OUT_OF_MEMORY</i> - there was a memory error. <i>TR_SUCCESS</i> , <i>TR_INVALID_OPTION</i> , and <i>TR_OUT_OF_MEMORY</i> are defined in <i>mkl_rci.fi</i> (Fortran) and <i>mkl_rci.h</i> (C) include files.

?jacobi_solve

Computes the Jacobian matrix of the function using RCI and the central difference algorithm.

Syntax**Fortran:**

```
res = sjacobi_solve(handle, f1, f2, RCI_Request)
res = djacobi_solve(handle, f1, f2, RCI_Request)
```

C:

```
res = sjacobi_solve(&handle, f1, f2, &RCI_Request);
res = djacobi_solve(&handle, f1, f2, &RCI_Request);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?jacobi_solve routine computes the Jacobian matrix of the function using RCI and the central difference algorithm.

See usage examples in FORTRAN and C in the examples\solver\source folder of your Intel MKL directory (sjacobi_rci_f.f, djacobi_rci_f.f and sjacobi_rci_c.c, djacobi_rci_c.c, respectively).

Input Parameters

handle Type _JACOBIMATRIX_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

Output Parameters

f1 REAL for sjacobi_solve
DOUBLE PRECISION for djacobi_solve
Contains the updated function values at $x + \text{eps}$.

f2 REAL for sjacobi_solve
DOUBLE PRECISION for djacobi_solve
Array of size m . Contains the updated function values at $x - \text{eps}$.

RCI_Request INTEGER. Informs about the task completion. When equal to 0, the task has completed successfully.
 $RCI_Request = 1$ indicates that you should compute the function values at the current x point and put the results into *f1*.
 $RCI_Request = 2$ indicates that you should compute the function values at the current x point and put the results into *f2*.

res INTEGER. Indicates the task completion status.

- $res = \text{TR_SUCCESS}$ - the routine completed the task normally.
- $res = \text{TR_INVALID_OPTION}$ - there was an error in the input parameters.

TR_SUCCESS and TR_INVALID_OPTION are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

See Also

?jacobi_init

?jacobi_delete

Releases allocated data.

Syntax

Fortran:

```
res = sjacobi_delete(handle)
res = djacobi_delete(handle)
```

C:

```
res = sjacobi_delete(&handle);
```

```
res = djacobi_delete(&handle);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?jacobi_delete routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function [mkl_free_buffers](#).

Input Parameters

handle Type `_JACOBIMATRIX_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res `INTEGER`. Informs about the task completion.
res = TR_SUCCESS means the routine completed the task normally.
`TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?jacobi

Computes the Jacobian matrix of the objective function using the central difference algorithm.

Syntax

Fortran:

```
res = sjacobi(fcn, n, m, fjac, x, eps)
res = djacobi(fcn, n, m, fjac, x, eps)
```

C:

```
res = sjacobi(fcn, &n, &m, fjac, x, &eps);
res = djacobi(fcn, &n, &m, fjac, x, &eps);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?jacobi routine computes the Jacobian matrix for function *fcn* using the central difference algorithm. This routine has a "Black-Box" interface, where you input the objective function via parameters. Your objective function must have a fixed interface.

See calling and usage examples in FORTRAN and C in the `examples\solver\source` folder of your Intel MKL directory (`ex_nlsqp_f.f`, `ex_nlsqp_bc_f.f` and `ex_nlsqp_c.c`, `ex_nlsqp_bc_c.c`, respectively).

Input Parameters

fcn User-supplied subroutine to evaluate the function that defines the least squares problem. Call *fcn* (*m*, *n*, *x*, *f*) with the following parameters:

Parameter	Type	Description
Input Parameters		
<i>m</i>	INTEGER	Length of <i>f</i>
<i>n</i>	INTEGER	Length of <i>x</i>
<i>x</i>	REAL for sjacobi DOUBLE PRECISION for djacobi	Array of size <i>n</i> . Vector, at which the function is evaluated. The <i>fcn</i> function should not change this parameter.
Output Parameters		
<i>f</i>	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size <i>m</i> ; contains the function values at <i>x</i> .

You need to declare *fcn* as EXTERNAL in the calling program.

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	REAL for sjacobi DOUBLE PRECISION for djacobi
	Array of size <i>n</i> . Vector at which the function is evaluated.
<i>eps</i>	REAL for sjacobi DOUBLE PRECISION for djacobi
	Precision of the Jacobian matrix calculation.

Output Parameters

<i>fjac</i>	REAL for sjacobi DOUBLE PRECISION for djacobi
	Array of size (<i>m,n</i>). Contains the Jacobian matrix of the function.
<i>res</i>	INTEGER. Indicates task completion status.
	<ul style="list-style-type: none"> • <i>res</i> = TR_SUCCESS - the routine completed the task normally. • <i>res</i> = TR_INVALID_OPTION - there was an error in the input parameters. • <i>res</i> = TR_OUT_OF_MEMORY - there was a memory error.
	TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in <i>mkl_rci.fi</i> (Fortran) and <i>mkl_rci.h</i> (C) include files.

See Also

?jacobi

?jacobix

Alternative interface for ?jacobi function for passing additional data into the objective function.

Syntax

Fortran:

```
res = sjacobix(fcn, n, m, fjac, x, eps, user_data)
res = djacobix(fcn, n, m, fjac, x, eps, user_data)
```

C:

```
res = sjacobix(fcn, &n, &m, fjac, x, &eps, user_data);
res = djacobix(fcn, &n, &m, fjac, x, &eps, user_data);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?jacobix routine presents an alternative interface for the ?jacobi function that enables you to pass additional data into the objective function *fcn*.

See calling and usage examples in FORTRAN and C in the examples\solver\source folder of your Intel MKL directory (ex_nlsqp_f_x.f, ex_nlsqp_bc_f_x.f and ex_nlsqp_c_x.c, ex_nlsqp_bc_c_x.c, respectively).

Input Parameters

fcn User-supplied subroutine to evaluate the function that defines the least squares problem. Call *fcn* (*m, n, x, f, user_data*) with the following parameters:

Parameter	Type	Description
Input Parameters		
<i>m</i>	INTEGER	Length of <i>f</i>
<i>n</i>	INTEGER	Length of <i>x</i>
<i>x</i>	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size <i>n</i> . Vector, at which the function is evaluated. The <i>fcn</i> function should not change this parameter.
<i>user_data</i>	INTEGER*8, for Fortran void*, for C	(Fortran) Your additional data, if any. Otherwise, a dummy argument. (C) Pointer to your additional data, if any. Otherwise, a dummy argument.
Output Parameters		
<i>f</i>	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size <i>m</i> ; contains the function values at <i>x</i> .

You need to declare *fcn* as EXTERNAL in the calling program.

<i>n</i>	INTEGER. Length of <i>x</i> .
<i>m</i>	INTEGER. Length of <i>F</i> .
<i>x</i>	REAL for sjacobix DOUBLE PRECISION for djacobix Array of size <i>n</i> . Vector at which the function is evaluated.
<i>eps</i>	REAL for sjacobix DOUBLE PRECISION for djacobix Precision of the Jacobian matrix calculation.

user_data

(Fortran) INTEGER*8. Contains your additional data. If there is no additional data, this is a dummy argument.

(C) void*. Pointer to your additional data. If there is no additional data, this is a dummy argument.

Output Parameters

fjac

REAL for sjacobix

DOUBLE PRECISION for djacobix

Array of size (m, n). Contains the Jacobian matrix of the function.

res

INTEGER. Indicates task completion status.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

Support Functions

Intel® Math Kernel Library (Intel® MKL) support functions are used to:

- retrieve information about the current Intel MKL version
- additionally control the number of threads
- handle errors
- test characters and character strings for equality
- measure user time for a process and elapsed CPU time
- measure CPU frequency
- free memory allocated by Intel MKL memory management software
- facilitate easy linking

Functions described below are subdivided according to their purpose into the following groups:

[Version Information Functions](#)

[Threading Control Functions](#)

[Error Handling Functions](#)

[Equality Test Functions](#)

[Timing Functions](#)

[Memory Functions](#)

[Miscellaneous Utility Functions](#)

[Functions Supporting the Single Dynamic Library](#)

Table "Intel MKL Support Functions" contains the list of support functions common for Intel MKL.

Intel MKL Support Functions

Function Name	Operation
Version Information Functions	
<code>mkl_get_version</code>	Returns information about the active library version.
<code>mkl_get_version_string</code>	Returns information about the library version string.
Threading Control Functions	
<code>mkl_set_num_threads</code>	Specifies the number of threads to use.
<code>mkl_domain_set_num_threads</code>	Specifies the number of threads for a particular function domain.
<code>mkl_set_dynamic</code>	Enables Intel MKL to dynamically change the number of threads.
<code>mkl_get_max_threads</code>	Gets the number of threads targeted for parallelism.
<code>mkl_domain_get_max_threads</code>	Gets the number of threads targeted for parallelism for a particular function domain.
<code>mkl_get_dynamic</code>	Determines whether Intel MKL is enabled to dynamically change the number of threads.
Error Handling Functions	

Function Name	Operation
<code>xerbla</code>	Handles error conditions for the BLAS, LAPACK, VSL, VML routines.
<code>pixerbla</code>	Handles error conditions for the ScaLAPACK routines.
Equality Test Functions	
<code>lsame</code>	Tests two characters for equality regardless of the case.
<code>lsamen</code>	Tests two character strings for equality regardless of the case.
Timing Functions	
<code>second/dsecnd</code>	Returns user time for a process.
<code>mkl_get_cpu_clocks</code>	Returns elapsed CPU clocks.
<code>mkl_get_cpu_frequency</code>	Returns CPU frequency value in GHz.
<code>mkl_get_max_cpu_frequency</code>	Returns the maximum CPU frequency value in GHz.
<code>mkl_get_clocks_frequency</code>	Returns the frequency value in GHz based on constant-rate Time Stamp Counter.
Memory Functions	
<code>mkl_free_buffers</code>	Frees memory buffers.
<code>mkl_thread_free_buffers</code>	Frees memory buffers allocated only in the current thread.
<code>mkl_mem_stat</code>	Reports an amount of memory utilized by Intel MKL memory management software.
<code>mkl_disable_fast_mm</code>	Enables Intel MKL to dynamically turn off memory management.
<code>mkl_malloc</code>	Allocates the aligned memory buffer.
<code>mkl_free</code>	Frees the aligned memory buffer allocated by <code>MKL_malloc</code> .
Miscellaneous Utility Functions	
<code>mkl_progress</code>	Tracks computational progress of selective MKL routines.
<code>mkl_enable_instructions</code>	Deprecated. Allows Intel MKL to dispatch Intel® Advanced Vector Extensions (Intel® AVX) if run on the respective hardware (or simulation).
Functions Supporting the Single Dynamic Library (SDL)	
<code>mkl_set_interface_layer</code>	Sets the interface layer for Intel MKL at run time.
<code>mkl_set_threading_layer</code>	Sets the threading layer for Intel MKL at run time.
<code>mkl_set_xerbla</code>	Replaces the error handling routine. Use with SDL on Windows* OS.
<code>mkl_set_progress</code>	Replaces the progress information routine. Use with SDL on Windows* OS.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Using a Fortran Interface Module for Support Functions

To call a support function from your Fortran application, include one of the following statements in your code:

- INCLUDE mkl_service.fi or INCLUDE mkl.fi
- USE mkl_service

The USE statement references the mkl_service.mod interface module corresponding to your architecture and programming interface. The module provides an application programming interface to Intel MKL support entities, such as subroutines and constants. Because Fortran interface modules are compiler-dependent, Intel MKL offers the mkl_service.f90 source file for the module, as well as architecture-specific and interface-specific mkl_service modules precompiled with the Intel® Fortran or Intel® Visual Fortran compiler. These modules are available in the following subdirectories of the Intel MKL include directory:

Architecture, Interface	Subdirectory of the Intel MKL Installation Directory
IA-32	include\ia32
Intel® 64, LP64	include\intel64\lp64
Intel® 64, ILP64	include\intel64\ilp64

To ensure that your application searches the right module, specify the appropriate subdirectory during compilation as an additional directory for the include path (through the /I option on Windows* OS or the -I option on Linux* OS or Mac OS* X).

If you are using a non-Intel Fortran compiler, you need to build the module yourself by compiling the mkl_service.f90 file, available in the Intel MKL include directory.

For more information on compiler-dependent functions and modules, refer to the *Intel MKL User's Guide*.

Version Information Functions

Intel® MKL provides two methods for extracting information about the library version number:

- extracting a version string using the mkl_get_version_string function
- using the mkl_get_version function to obtain an MKLVersion structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

mkl_get_version

Returns information about the active library C version.

Syntax

```
void mkl_get_version( MKLVersion* pVersion );
```

Include Files

- C: mkl.h

Output Parameters

pVersion Pointer to the MKLVersion structure.

Description

The `mkl_get_version` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the *pVersion* address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

MajorVersion	is the major number of the current library version.
MinorVersion	is the minor number of the current library version.
UpdateVersion	is the update number of the current library version.
ProductStatus	is the status of the current library version. Possible variants could be "Beta", "Product".
Build	is the string that contains the build date and the internal build number.
Processor	is the processor optimization that is targeted for the specific processor. It is not the definition of the processor installed in the system, rather the MKL library detection that is optimal for the processor installed in the system.

NOTE `MKLGetVersion` is an obsolete name for the `mkl_get_version` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkl_get_version Usage

```
#include <stdio.h>
#include <stdlib.h>
#include "mkl_service.h"

int main(void)
{
    MKLVersion Version;

    mkl_get_version(&Version);

    // MKL_Get_Version(&Version);

    printf("Major version:          %d\n", Version.MajorVersion);
    printf("Minor version:          %d\n", Version.MinorVersion);
    printf("Update version:         %d\n", Version.UpdateVersion);
    printf("Product status:         %s\n", Version.ProductStatus);
    printf("Build:                  %s\n", Version.Build);
    printf("Processor optimization: %s\n", Version.Processor);
    printf("=====\\n");
    printf("\\n");

    return 0;
}
```

Output:

Major Version	9
Minor Version	0
Update Version	0
Product status	Product
Build	061909.09
Processor optimization	Intel® Xeon® Processor with Intel® 64 architecture

mkl_get_version_string

Gets the library version string.

Syntax

Fortran:

```
call mkl_get_version_string( buf )
```

C:

```
void mkl_get_version_string (char* buf, int len);
```

Include Files/Modules

- Fortran include file: mkl.fi
- Fortran module (compiled): mkl_service.mod
- Fortran module (source): mkl_service.f90
- C include file: mkl.h

Output Parameters

Name	Type	Description
<i>buf</i>	FORTRAN: CHARACTER*198 C: char*	Source string
<i>len</i>	C: int	Length of the source string

Description

The function returns a string that contains the library version information.

NOTE MKLGetString is an obsolete name for the mkl_get_version_string function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

See example below:

Examples

Fortran Example

```
program mkl_get_version_string
character*198  buf
call mkl_get_version_string(buf)
write(*,1(a)1) buf
end
```

C Example

```
#include <stdio.h>
#include "mkl_service.h"

int main(void)
{
    int len=198;
    char buf[198];
    mkl_get_version_string(buf, len);
    printf("%s\n",buf);
    printf("\n");
    return 0;
}
```

Threading Control Functions

Intel® MKL computational functions can create internal regions for parallel execution. Because Intel MKL operates within an OpenMP* execution environment, you can control the number of threads for Intel MKL using OpenMP* run-time library routines and environment variables (see the OpenMP* specification for

details). Additionally Intel MKL provides *optional* threading control functions and environment variables that enable you to specify the number of threads for Intel MKL and to control dynamic adjustment of the number of threads *independently* of the OpenMP* settings. The settings made with the Intel MKL threading control functions and environment variables do not affect OpenMP* settings but take precedence over them.

This section describes how to control the number of threads using Intel MKL functions for threading control. If none of the threading control functions is used, Intel MKL environment variables may control Intel MKL threading. For details of those environment variables, see the *Intel MKL User's Guide*.

You can specify the number of threads for Intel MKL function domains with the `mkl_set_num_threads` or `mkl_domain_set_num_threads` function. While `mkl_set_num_threads` specifies the number of threads for the entire Intel MKL, `mkl_domain_set_num_threads` does it for a specific function domain. The following table lists the function domains that support independent threading control. The table also provides named constants to pass to threading control functions as a parameter that specifies the function domain.

Intel MKL Function Domains

Function Domain	Named Constant
Basic Linear Algebra Subroutines (BLAS)	<code>MKL_DOMAIN_BLAS</code>
Fast Fourier Transform (FFT) functions, except Cluster FFT functions	<code>MKL_DOMAIN_FFT</code>
Vector Math Library (VML) Functions	<code>MKL_DOMAIN_VML</code>
Parallel Direct Solver (PARDISO) functions	<code>MKL_DOMAIN_PARDISO</code>
All Intel MKL functions except the functions from those of the above domains for which the number of threads is set explicitly	<code>MKL_DOMAIN_ALL</code>

By default, Intel MKL can adjust the specified number of threads dynamically. For example, Intel MKL may use fewer threads if the size of the computation is not big enough or not create parallel regions when running within an OpenMP* parallel region. Although Intel MKL may actually use a different number of threads from the number specified, the library does not create parallel regions with more threads than specified. If dynamic adjustment of the number of threads is disabled, Intel MKL attempts to use the specified number of threads in internal parallel regions (for more information, see the *Intel MKL User's Guide*). Use the `mkl_set_dynamic` function to control dynamic adjustment of the number of threads.

`mkl_set_num_threads`

Specifies the number of threads to use.

Syntax

Fortran:

```
call mkl_set_num_threads( nt )
```

C:

```
void mkl_set_num_threads( int nt );
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<i>nt</i>	FORTRAN: INTEGER	$nt > 0$ - The number of threads suggested by the user.
C: int		$nt \leq 0$ - Invalid value, which is ignored.

Description

This function allows you to specify how many threads Intel MKL should use for internal parallel regions. If this number is not set (default), Intel MKL functions use the OpenMP* number of threads. The specified number of threads applies to all Intel MKL functions except the functions from the domains where the number of threads is set with [mkl_domain_set_num_threads](#).

The number specified is a hint, and Intel MKL may actually use a different number.

NOTE This function takes precedence over the `MKL_NUM_THREADS` environment variable.

Examples

```
// C/C++
#include "mkl_service.h"
...
mkl_set_num_threads(4);
my_compute_using_mkl(); // Intel MKL uses up to 4 threads

! Fortran
use mkl_service
...
call mkl_set_num_threads(4)
call my_compute_using_mkl !Intel MKL uses up to 4 threads
```

See Also

[Using a Fortran Interface Module for Support Functions](#)

[mkl_domain_set_num_threads](#)

Specifies the number of threads for a particular function domain.

Syntax

Fortran:

```
ierr = mkl_domain_set_num_threads( nt, domain )
```

C:

```
int mkl_domain_set_num_threads (int nt, int domain);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<i>nt</i>	FORTRAN: INTEGER C: int	<i>nt</i> > 0 - The number of threads suggested by the user. <i>nt</i> = 0 - A request to reset the number of threads and use the OpenMP* number of threads. <i>nt</i> < 0 - Invalid value, which is ignored.
<i>domain</i>	FORTRAN: INTEGER C: int	The named constant that defines the targeted domain.

Description

This function specifies how many threads a particular function domain of Intel MKL should use. If this number is not set (default) or if it is set to zero in a call to this function, Intel MKL will use the OpenMP* number of threads. For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

The number of threads specified is only a hint, and Intel MKL may actually use a different number.

NOTE This function takes precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

Return Values

Name	Type	Description
<i>ierr</i>	FORTRAN: INTEGER C: int	1 - Indicates no error, execution is successful. 0 - Indicates a failure, possibly because of invalid input parameters.

Examples

```
// C/C++
#include "mkl_service.h"
...
mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS);
my_compute_using_mkl blas();           // Intel MKL BLAS functions use up to 4 threads
my_compute_using_mkl dft();           // Intel MKL FFT functions use the default number of threads

! Fortran
use mkl_service
integer(4) :: status
...
status = mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS)
call my_compute_with_mkl blas()        ! Intel MKL BLAS functions use up to 4 threads
call my_compute_with_mkl dft()         ! Intel MKL FFT functions use the default number of threads
```

See Also

[Using a Fortran Interface Module for Support Functions](#)

[**mkl_set_dynamic**](#)

Enables Intel MKL to dynamically change the number of threads.

Syntax

Fortran:

```
call mkl_set_dynamic( flag )
```

C:

```
void mkl_set_dynamic (int flag);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<i>flag</i>	FORTRAN: INTEGER C: int	<i>flag</i> = 0 - Requests disabling dynamic adjustment of the number of threads. <i>flag</i> ≠ 0 - Requests enabling dynamic adjustment of the number of threads.

Description

This function indicates whether Intel MKL can dynamically change the number of threads or should avoid doing this. The setting applies to all Intel MKL functions. This function takes precedence over the `MKL_DYNAMIC` environment variable.

Dynamic adjustment of the number of threads is enabled by default. Specifically, Intel MKL may use fewer threads in parallel regions than the number returned by the `mkl_get_max_threads` function. Disabling dynamic adjustment of the number of threads does not ensure that Intel MKL actually uses the specified number of threads, although the library attempts to use that number.

TIP If you call Intel MKL from within an OpenMP* parallel region and want to create internal parallel regions, disable dynamic adjustment of the number of threads.

Examples

```
// C/C++
#include "mkl_service.h"
...
mkl_set_num_threads( 8 );
#pragma omp parallel
{
    my_compute_with_mkl();      // Intel MKL uses 1 thread, being called from OpenMP parallel region
    mkl_set_dynamic( 0 );      // disable adjustment of the number of threads
    my_compute_with_mkl();      // Intel MKL uses 8 threads
}

! Fortran
use mkl_service
...
call mkl_set_num_threads( 8 )
 !$omp parallel
    call my_compute_with_mkl      ! Intel MKL uses 1 thread, being called from OpenMP parallel region
    call mkl_set_dynamic(0)       ! disable adjustment of the number of threads
    call my_compute_with_mkl     ! Intel MKL uses 8 threads
 !$omp end parallel
```

See Also

[Using a Fortran Interface Module for Support Functions](#)

mkl_get_max_threads

Gets the number of threads targeted for parallelism.

Syntax

Fortran:

```
nt = mkl_get_max_threads()
```

C:

```
int mkl_get_max_threads (void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

This function returns the number of threads for Intel MKL to use in internal parallel regions. To determine this number, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- The last of the calls to `mkl_set_num_threads` or `mkl_domain_set_num_threads(..., MKL_DOMAIN_ALL)`
- The `MKL_DOMAIN_NUM_THREADS` environment variable with the `MKL_ALL` tag
- The `MKL_NUM_THREADS` environment variable
- A call to `omp_set_num_threads`
- The `OMP_NUM_THREADS` environment variable

The number of threads returned by this function is a hint, and Intel MKL may actually use a different number.

Return Values

Name	Type	Description
<code>nt</code>	FORTRAN: INTEGER*4 C: int	The maximum number of threads for Intel MKL functions to use in internal parallel regions.

Examples

```
// C/C++
#include "mkl_service.h"
...
if (1 == mkl_get_max_threads()) puts("Intel MKL does not employ threading");

! Fortran
use mkl_service
...
if (1 == mkl_get_max_threads()) print *, "Intel MKL does not employ threading"
```

See Also

[Using a Fortran Interface Module for Support Functions](#)

mkl_domain_get_max_threads

Gets the number of threads targeted for parallelism for a particular function domain.

Syntax

Fortran:

```
nt = mkl_domain_get_max_threads( domain )
```

C:

```
int mkl_domain_get_max_threads (int domain);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<code>domain</code>	FORTRAN: INTEGER C: int	The named constant that defines the targeted domain.

Description

Computational functions of the Intel MKL function domain defined by the `domain` parameter use the value returned by this function as a limit of the number of threads they should request for parallel computations. To determine this number, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- The last of the calls to `mkl_set_num_threads` or `mkl_domain_set_num_threads(..., MKL_DOMAIN_ALL)`
- A call to `mkl_domain_set_num_threads(..., domain)`
- The `MKL_DOMAIN_NUM_THREADS` environment variable with the `MKL_ALL` tag
- The `MKL_DOMAIN_NUM_THREADS` environment variable (with the specific domain tag)
- The `MKL_NUM_THREADS` environment variable
- A call to `omp_set_num_threads`
- The `OMP_NUM_THREADS` environment variable

Actual number of threads used by the Intel MKL computational functions may vary depending on the problem size and on whether dynamic adjustment of the number of threads is enabled (see the description of `mkl_set_dynamic`). For a list of supported values of the `domain` argument, see [Table "Intel MKL Function Domains"](#).

Return Values

Name	Type	Description
<code>nt</code>	FORTRAN: INTEGER*4 C: int	The maximum number of threads for Intel MKL functions from a given domain to use in internal parallel regions. If an invalid value of <code>domain</code> is supplied, the function returns the number of threads for <code>MKL_DOMAIN_ALL</code>

Examples

```
// C/C++
#include "mkl_service.h"
...
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS))
puts("Intel MKL BLAS functions employ threading");

! Fortran
use mkl_service
...
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS)) then
print *, "Intel MKL BLAS functions employ threading"
end if
```

See Also

[Using a Fortran Interface Module for Support Functions](#)

mkl_get_dynamic

Determines whether Intel MKL is enabled to dynamically change the number of threads.

Syntax

Fortran:

```
ret = mkl_get_dynamic()
```

C:

```
int mkl_get_dynamic(void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

This function returns the status of dynamic adjustment of the number of threads. To determine this status, the function inspects the return value of the following function call and if it is undefined, inspects the environment setting below:

- A call to `mkl_set_dynamic`
- The `MKL_DYNAMIC` environment variable

NOTE Dynamic adjustment of the number of threads is enabled by default.

The dynamic adjustment works as follows. Suppose that the `mkl_get_max_threads` function returns the number of threads equal to N . If dynamic adjustment is enabled, Intel MKL may request up to N threads, depending on the size of the problem. If dynamic adjustment is disabled, Intel MKL requests exactly N threads for internal parallel regions (provided it uses a threaded algorithm with at least N computations that can be done in parallel). However, the OpenMP* run-time library may be configured to supply fewer threads than Intel MKL requests, depending on the OpenMP* setting of dynamic adjustment.

Return Values

Name	Type	Description
<i>ret</i>	FORTRAN: INTEGER*4	0 - Dynamic adjustment of the number of threads is disabled.
	C: int	1 - Dynamic adjustment of the number of threads is enabled.

Examples

```
// C/C++
#include "mkl_service.h"
...
int nt = mkl_get_max_threads();
if (1 == mkl_get_dynamic())
printf("Intel MKL may use less than %i threads for a large problem", nt);
else
printf("Intel MKL should use %i threads for a large problem", nt);

! Fortran
use mkl_service
integer(4) :: nt
...
nt = mkl_get_max_threads()
if (1 == mkl_get_dynamic()) then
  print'("Intel MKL may use less than "IO" threads for a large problem")', nt
else
  print'("Intel MKL should use "IO" threads for a large problem")', nt
end if
```

Error Handling Functions

xerbla

Error handling routine called by BLAS, LAPACK, VML, VSL routines.

Syntax

Fortran:

```
call xerbla( srname, info )
```

C:

```
void xerbla( const char * srname, const int* info, const int len );
```

Include Files

- **Fortran:** mkl.fi
- **C:** mkl.h

Input Parameters

Name	Type	Description
<i>srname</i>	FORTRAN: CHARACTER* (*) C: const char*	The name of the routine that called <code>xerbla</code>
<i>info</i>	FORTRAN: INTEGER C: const int*	The position of the invalid parameter in the parameter list of the calling routine
C: <i>len</i>	const int	Length of the source string

Description

The routine `xerbla` is an error handler for the BLAS, LAPACK, VSL, and VML routines. It is called by a BLAS, LAPACK, VSL or VML routine if an input parameter has an invalid value. If an issue is found with an input parameter, `xerbla` prints a message similar to the following:

```
MKL ERROR: Parameter 6 was incorrect on entry to DGEMM
```

and then returns to your application. Comments in the LAPACK reference code (<http://www.netlib.org/lapack/explore-html/xerbla.f.html>) suggest this behavior though the LAPACK User's Guide recommends that the execution should stop when an error is found.

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. See the FORTRAN and C examples below.

Examples

```
subroutine xerbla (srname, info)
character*(*) srname !Name of subprogram that called xerbla
integer*4 info !Position of the invalid parameter in the
parameter list
return !Return to the calling subprogram
end

void xerbla(char* srname, int* info, int len){
// srname - name of the function that called xerbla
// info - position of the invalid parameter in the parameter list
// len - length of the name in bytes
printf("\nXERBLA is called :%s: %d\n",srname,*info);
}
```

pXerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
void pXerbla(MKL_INT* ictxt, char* srname, MKL_INT* info)
```

Include Files

- C: mkl_scalapack.h

Input Parameters

<i>ictxt</i>	(global) MKL_INT
	The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>srname</i>	(global) char
	The name of the routine which called <code>pixerbla</code> .
<i>info</i>	(global) MKL_INT.
	The position of the invalid parameter in the parameter list of the calling routine.

Description

This routine is an error handler for the *ScalAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For *ScalAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `pixerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level *ScalAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pixerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *info* on return from a *ScalAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Equality Test Functions

Isame

Tests two characters for equality regardless of the case.

Syntax

Fortran:

```
val = lsame( ca, cb )
```

C:

```
int lsame( const char* ca, const char* cb, int lca, int lcb );
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>ca, cb</i>	FORTRAN: CHARACTER*1 C: const char*	FORTRAN: The single characters to be compared C: Pointers to the single characters to be compared
C: <i>lca, lcb</i> int		Lengths of the input character strings, equal to one.

Description

This logical function returns `.TRUE.` if `ca` is the same letter as `cb` regardless of the case, and `.FALSE.` otherwise.

Return Values

Name	Type	Description
<code>val</code>	FORTRAN: LOGICAL C: int	Result of the comparison

Isamen

Tests two character strings for equality regardless of the case.

Syntax

Fortran:

```
val = lsamen( n, ca, cb )
```

C:

```
MKL_INT lsamen( const MKL_INT* n, const char* ca, const char* cb );
```

Include Files

- Fortran: `mkl.fi`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>n</code>	FORTRAN: INTEGER C: const MKL_INT*	FORTRAN: The number of characters in <code>ca</code> and <code>cb</code> to be compared. C: Pointer to the number of characters in <code>ca</code> and <code>cb</code> to be compared.
<code>ca, cb</code>	FORTRAN: CHARACTER* (*) C: const char*	Specify two character strings of length at least <code>n</code> to be compared. Only the first <code>n</code> characters of each string will be accessed.

Description

This logical function tests if the first `n` letters of one string are the same as the first `n` letters of another string, regardless of the case.

Return Values

Name	Type	Description
<code>val</code>	FORTRAN: LOGICAL C: MKL_INT	FORTRAN: Result of the comparison. <code>.TRUE.</code> if <code>ca</code> and <code>cb</code> are equivalent except for the case, and <code>.FALSE.</code> otherwise. The function also returns <code>.FALSE.</code> if <code>len(ca)</code> or <code>len(cb)</code> is less than <code>n</code> .

Name	Type	Description
		C: Result of the comparison. Non-zero if <i>ca</i> and <i>cb</i> are equivalent except for the case, and zero otherwise.

Timing Functions

second/dsecnd

Returns elapsed CPU time in seconds.

Syntax

Fortran:

```
val = second()
val = dsecnd()
```

C:

```
float second( void );
double dsecnd( void );
```

Include Files

- Fortran: mkl.fi
- C: mkl.h

Description

The `second/dsecnd` functions return the elapsed CPU time in seconds. The difference between these functions is that `dsecnd` returns the result with double precision.

Apply each function in pairs: the first time, directly before a call to the routine to be measured, and the second time - after the measurement. The difference between the returned values is the time spent in the routine.

The `second/dsecnd` functions get the time from the elapsed CPU clocks divided by frequency. Obtaining the frequency may take some time when the `second/dsecnd` function runs for the first time. To eliminate the effect of this extra time on your measurements, make the first call to `second/dsecnd` in advance.

Do not use `second` for measuring short time intervals because the single-precision format is not capable of holding sufficient timer precision.

Return Values

Name	Type	Description
<i>val</i>	FORTRAN: REAL for <code>second</code> DOUBLE PRECISION for <code>dsecnd</code>	Elapsed CPU time in seconds
	C: float for <code>second</code> double for <code>dsecnd</code>	

mkl_get_cpu_clocks

Returns elapsed CPU clocks.

Syntax

Fortran:

```
call mkl_get_cpu_clocks( clocks )
```

C:

```
void mkl_get_cpu_clocks (unsigned MKL_INT64 *clocks);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Output Parameters

Name	Type	Description
<i>clocks</i>	FORTRAN: INTEGER*8 C: unsigned MKL_INT64	Elapsed CPU clocks

Description

The `mkl_get_cpu_clocks` function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `mkl_get_cpu_clocks` function is also applied in pairs like `second/dsecnd`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

NOTE `getcpuclocks` is an obsolete name for the `mkl_get_cpu_clocks` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkl_get_cpu_frequency

Returns the current CPU frequency value in GHz.

Syntax

Fortran:

```
freq = mkl_get_cpu_frequency()
```

C:

```
double mkl_get_cpu_frequency(void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

The function `mkl_get_cpu_frequency` returns the current CPU frequency in GHz.

NOTE `getcpufrequency` is an obsolete name for the `mkl_get_cpu_frequency` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

Return Values

Name	Type	Description
<code>freq</code>	FORTRAN: DOUBLE PRECISION C: double	Current CPU frequency value in GHz

See Also

[Using a Fortran Interface Module for Support Functions](#)

[`mkl_get_max_cpu_frequency`](#)

Returns the maximum CPU frequency value in GHz.

Syntax

Fortran:

```
freq = mkl_get_max_cpu_frequency()
```

C:

```
double mkl_get_max_cpu_frequency(void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

The function `mkl_get_max_cpu_frequency` returns the maximum CPU frequency in GHz.

Return Values

Name	Type	Description
<i>freq</i>	FORTRAN: DOUBLE PRECISION C: double	Maximum CPU frequency value in GHz

See Also

[Using a Fortran Interface Module for Support Functions](#)

mkl_get_clocks_frequency

Returns the frequency value in GHz based on constant-rate Time Stamp Counter.

Syntax

Fortran:

```
freq = mkl_get_clocks_frequency()
```

C:

```
double mkl_get_clocks_frequency (void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

The function `mkl_get_clocks_frequency` returns the CPU frequency value (in GHz) based on constant-rate Time Stamp Counter (TSC). Use of the constant-rate TSC ensures that each clock tick is constant even if the CPU frequency changes. Therefore, the returned frequency is constant.

NOTE Obtaining the frequency may take some time when `mkl_get_clocks_frequency` is called for the first time. The same holds for functions `second/dsecnd`, which call `mkl_get_clocks_frequency`.

Return Values

Name	Type	Description
<i>freq</i>	FORTRAN: DOUBLE PRECISION C: double	Frequency value in GHz

See Also

`second/dsecnd`

[Using a Fortran Interface Module for Support Functions](#)

Memory Functions

This section describes the Intel MKL memory support functions. See the *Intel® MKL User's Guide* for details of the Intel MKL memory management.

mkl_free_buffers

Frees memory buffers.

Syntax

Fortran:

```
call mkl_free_buffers
```

C:

```
void mkl_free_buffers (void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

The `mkl_free_buffers` function frees the memory allocated by the Intel MKL memory management software. The memory management software allocates new buffers if no free buffers are currently available. Call `mkl_free_buffers()` to free all memory buffers and to avoid memory leaking on completion of work with the Intel MKL functions, that is, after the last call of an Intel MKL function from your application.

See *Intel® MKL User's Guide* for details.

NOTE `MKL_FreeBuffers` is an obsolete name for the `mkl_free_buffers` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_free_buffers Usage with FFT Functions

```
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
. . . .
/* Using MKL FFT */

Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
. . . .
Status = DftiFreeDescriptor(&hand1);
/* Do not call mkl_free_buffers() here as the hand2 descriptor will be corrupted! */
. . . .
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);

/* Here user finishes the MKL FFT usage */
/* Memory leak will be triggered by any memory control tool */

/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();
```

If the memory space is sufficient, use `mkl_free_buffers` after the last call of the MKL functions. Otherwise, a drop in performance can occur due to reallocation of buffers for the subsequent MKL functions.

WARNING For FFT calls, do not use `mkl_free_buffers` between `DftiCreateDescriptor(hand)` and `DftiFreeDescriptor(&hand)`.

See Also

Using a Fortran Interface Module for Support Functions

mkl_thread_free_buffers

Frees memory buffers allocated in the current thread.

Syntax

Fortran:

```
call mkl_thread_free_buffers
```

C:

```
void mkl_thread_free_buffers (void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

The `mkl_thread_free_buffers` function frees the memory allocated by the Intel MKL memory management in the current thread only. Memory buffers allocated in other threads are not affected. Call `mkl_thread_free_buffers()` to avoid memory leaking if you are unable to call the `mkl_free_buffers` function in the multi-threaded application when you are not sure if all the other running Intel MKL functions completed operation.

See Also

[Using a Fortran Interface Module for Support Functions](#)

`mkl_disable_fast_mm`

Enables Intel MKL to dynamically turn off memory management.

Syntax

Fortran:

```
mm = mkl_disable_fast_mm
```

C:

```
int mkl_disable_fast_mm (void);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Description

The Intel MKL memory management software is turned on by default. To turn it off dynamically before any Intel MKL function call, you can use the `mkl_disable_fast_mm` function similarly to the `MKL_DISABLE_FAST_MM` environment variable (See *Intel® MKL User's Guide* for details.) Run `mkl_disable_fast_mm` function to allocate and free memory from call to call. Note that disabling the Intel MKL memory management software negatively impacts performance of some Intel MKL routines, especially for small problem sizes.

The function return value 1 indicates that the Intel MKL memory management was turned off successfully. The function return value 0 indicates a failure.

See Also

[Using a Fortran Interface Module for Support Functions](#)

mkl_mem_stat

Reports amount of memory utilized by Intel MKL memory management software.

Syntax

Fortran:

```
AllocatedBytes = mkl_mem_stat( AllocatedBuffers )
```

C:

```
MKL_INT64 mkl_mem_stat (int* AllocatedBuffers);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Output Parameters

Name	Type	Description
<code>AllocatedBuffers</code>	FORTRAN: INTEGER*4, C: int	Number of allocated buffers

Description

The function returns the amount of the allocated memory in the `AllocatedBuffers` buffers. If there are no allocated buffers at the moment, the function returns 0. Call the `mkl_mem_stat()` function to check the Intel MKL memory status.

Note that after calling `mkl_free_buffers` there should not be any allocated buffers.

See [Example "mkl_malloc\(\), mkl_free\(\), mkl_mem_stat\(\) Usage"](#).

NOTE `MKL_MemStat` is an obsolete name for the `MKL_Mem_Stat` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

Return Values

Name	Type	Description
<code>AllocatedBytes</code>	FORTRAN: INTEGER*8 C: MKL_INT64	Amount of allocated bytes

See Also

[Using a Fortran Interface Module for Support Functions](#)

mkl_malloc

Allocates the aligned memory buffer.

Syntax

Fortran:

```
a_ptr = mkl_malloc( alloc_size, alignment )
```

C:

```
void* mkl_malloc (size_t alloc_size, int alignment);
```

Include Files/Modules

- Fortran include file: mkl.fi
- Fortran module (compiled): mkl_service.mod
- Fortran module (source): mkl_service.f90
- C include file: mkl.h

Input Parameters

Name	Type	Description
<i>alloc_size</i>	FORTRAN: INTEGER*4 C: size_t	Size of the buffer to be allocated. Note that Fortran type INTEGER*4 is given for the 32-bit systems. Otherwise, it is INTEGER*8.
<i>alignment</i>	FORTRAN: INTEGER*4 C: int	Alignment of the allocated buffer

Description

The function allocates a *size*-bytes buffer, aligned on the *alignment* boundary, and returns a pointer to this buffer.

The function returns NULL if *size* < 1. If alignment is not power of 2, the alignment 32 is used.

See [Example "mkl_malloc\(\), mkl_free\(\), mkl_mem_stat\(\) Usage"](#).

Return Values

Name	Type	Description
<i>a_ptr</i>	FORTRAN: POINTER C: void*	Pointer to the allocated buffer

See Also

[Using a Fortran Interface Module for Support Functions](#)

mkl_free

Frees the aligned memory buffer allocated by mkl_malloc.

Syntax

Fortran:

```
call mkl_free( a_ptr )
```

C:

```
void mkl_free (void *a_ptr);
```

Include Files/Modules

- Fortran include file: mkl.fi
- Fortran module (compiled): mkl_service.mod
- Fortran module (source): mkl_service.f90
- C include file: mkl.h

Input Parameters

Name	Type	Description
a_ptr	FORTRAN: POINTER C: void*	Pointer to the buffer to be freed

Description

The function frees the buffer pointed by *ptr* and allocated by mkl_malloc().

See [Example "mkl_malloc\(\), mkl_free\(\), mkl_mem_stat\(\) Usage"](#).

use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkl_progress

Provides progress information.

Syntax

Fortran:

```
stopflag = mkl_progress( thread, step, stage )
```

C:

```
int mkl_progress (int* thread, int* step, char* stage, int lstage);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<code>thread</code>	FORTRAN: INTEGER*4 C: const int*	FORTRAN: The number of the thread the progress routine is called from. 0 is passed for sequential code. C: Pointer to the number of the thread the progress routine is called from. 0 is passed for sequential code.
<code>step</code>	FORTRAN: INTEGER*4 C: const int*	FORTRAN: The linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation. C: Pointer to the linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
<code>stage</code>	FORTRAN: CHARACTER* (*) C: const char*	Message indicating the name of the routine or the name of the computation stage the progress routine is called from.
<code>lstage</code>	C: int	The length of a stage string excluding the trailing NULL character.

Description

The `mkl_progress` function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

The progress function `mkl_progress` is regularly called from some LAPACK and DSS/PARDISO functions during the computation. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

Return Values

Name	Type	Description
<code>stopflag</code>	FORTRAN: INTEGER C: int	The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.

Application Notes

Note that `mkl_progress` is a Fortran routine, that is, to redefine the progress routine from C, the name should be spelt differently, parameters should be passed by reference, and an extra parameter meaning the length of the stage string should be considered. The stage string is not terminated with the `\0` character. The C interface of the progress routine is as follows:

```
int mkl_progress_( int* thread, int* step, char* stage, int lstage ); // Linux, Mac
int MKL_PROGRESS( int* thread, int* step, char* stage, int lstage ); // Windows
```

See further the examples of printing a progress information on the standard output in Fortran and C languages:

Examples

Fortran example:

```
integer function mkl_progress( thread, step, stage )
integer*4 thread, step
character(*) stage
print*, 'Thread:', thread, ',stage:', stage, ',step:', step
mkl_progress = 0
return
end
```

C example:

```
#include <stdio.h>
#include <string.h>
#define BUflen 16
int mkl_progress_( int* ithr, int* step, char* stage, int lstage )
{
    char buf[BUflen];
    if( lstage >= BUflen ) lstage = BUflen-1;
    strncpy( buf, stage, lstage );
    buf[lstage] = '\0';
    printf( "In thread %i, at stage %s, steps passed %i\n", *ithr, buf, *step );
    return 0;
}
```

`mkl_enable_instructions`

Allows dispatching Intel® Advanced Vector Extensions (Intel® AVX).

Syntax

Fortran:

```
irc = mkl_enable_instructions(MKL_AVX_ENABLE)
```

C:

```
int mkl_enable_instructions (int MKL_AVX_ENABLE);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

`MKL_AVX_ENABLE` Parameter indicating which new instructions the user needs to enable.

Description

This function is currently void and deprecated but can be used in future Intel MKL releases.

NOTE Always remember to add `#include "mkl.h"` to use the C usage syntax.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

Name	Type	Description
<i>irc</i>	FORTRAN: INTEGER*4 C: int	Value reflecting Intel AVX usage status: =1 Intel MKL uses Intel AVX code if the hardware supports Intel AVX. =0 The request is rejected. Most likely, <code>mkl_enable_instructions</code> has been called after another Intel MKL function.

Functions Supporting the Single Dynamic Library

Intel® MKL provides the Single Dynamic Library (SDL), which enables setting the interface and threading layer for Intel MKL at run time. See *Intel® MKL User's Guide* for details of SDL and layered model concept. This section describes the functions supporting SDL.

`mkl_set_interface_layer`

Sets the interface layer for Intel MKL at run time. Use with the Single Dynamic Library.

Syntax

Fortran:

```
interface = mkl_set_interface_layer( required_interface )
```

C:

```
int mkl_set_interface_layer (int required_interface);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<code>required_interface</code>	FORTRAN: INTEGER C: int	Determines the interface layer. Possible values: <code>MKL_INTERFACE_LP64</code> for the LP64 interface. <code>MKL_INTERFACE_ILP64</code> for the ILP64 interface.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_interface_layer` function sets LP64 or ILP64 interface for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_threading_layer`. You can call `mkl_set_interface_layer` and `mkl_set_threading_layer` in any order.

The `mkl_set_interface_layer` function takes precedence over the `MKL_INTERFACE_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of SDL.

See Also

[Using a Fortran Interface Module for Support Functions](#)

`mkl_set_threading_layer`

Sets the threading layer for Intel MKL at run time. Use with the Single Dynamic Library (SDL).

Syntax

Fortran:

```
threading = mkl_set_threading_layer( required_threading )
```

C:

```
int mkl_set_threading_layer (int required_threading);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`

- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<code>required_threading</code>	FORTRAN: INTEGER C: int	Determines the threading layer. Possible values: MKL_THREADING_INTEL for Intel threading. MKL_THREADING_SEQUENTIAL for the sequential mode of Intel MKL. MKL_THREADING_PGI for PGI threading on Windows* or Linux* operating system only. MKL_THREADING_GNU for GNU threading on Linux* operating system only.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_threading_layer` function sets the specified threading layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_interface_layer`.

You can call `mkl_set_threading_layer` and `mkl_set_interface_layer` in any order.

The `mkl_set_threading_layer` function takes precedence over the `MKL_THREADING_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of SDL.

`mkl_set_xerbla`

Replaces the error handling routine. Use with the Single Dynamic Library on Windows OS.*

Syntax

Fortran:

```
old_xerbla_ptr = mkl_set_xerbla( new_xerbla_ptr )
```

C:

```
XerblaEntry mkl_set_xerbla (XerblaEntry new_xerbla_ptr);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<code>new_xerbla_ptr</code>	XerblaEntry	Pointer to the error handling routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_xerbla` function replaces the error handling routine that is called by Intel MKL functions with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced error handling routine.

See Also

`xerbla`

[Using a Fortran Interface Module for Support Functions](#)

`mkl_set_progress`

Replaces the progress information routine. Use with the Single Dynamic Library (SDL) on Windows OS.*

Syntax

Fortran:

```
old_progress_ptr mkl_set_progress( new_progress_ptr )
```

C:

```
ProgressEntry mkl_set_progress (ProgressEntry new_progress_ptr);
```

Include Files/Modules

- Fortran include file: `mkl.fi`
- Fortran module (compiled): `mkl_service.mod`
- Fortran module (source): `mkl_service.f90`
- C include file: `mkl.h`

Input Parameters

Name	Type	Description
<code>new_progress_ptr</code>	ProgressEntry	Pointer to the progress information routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_progress` function replaces the currently used progress information routine with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced progress information routine.

[Using a Fortran Interface Module for Support Functions](#)

BLACS Routines

This chapter describes the Intel® Math Kernel Library implementation of FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux* and Windows* OSs as the communication layer of ScalAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of m rows and n columns, with a leading dimension, lda , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

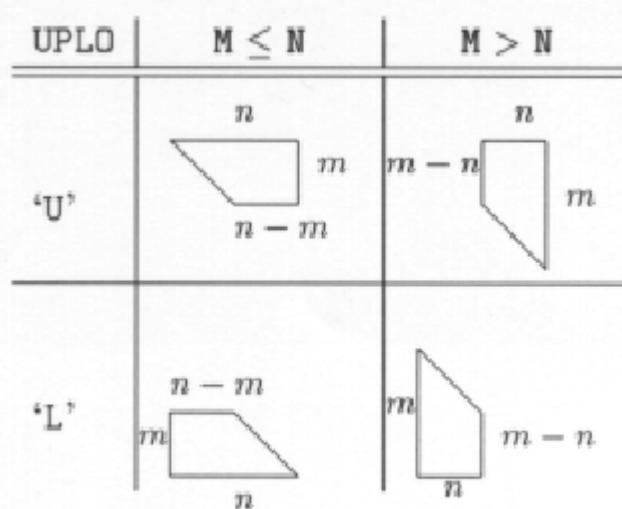

m	(input) INTEGER. The number of matrix rows to be operated on.
n	(input) INTEGER. The number of matrix columns to be operated on.
a	(input/output) TYPE (depends on routine), array of dimension (lda, n). A pointer to the beginning of the (sub)array to be sent.
lda	(input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by m , n , and lda , as above, but they have two additional parameters as well. These parameters are:

$uplo$	(input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.
$diag$	(input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

Trapezoidal Arrays Shapes

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (`max/min/sum`) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4×2 array of inputs produces a 4×2 answer array.

When the `max/min` comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

i	integer
s	single precision real

d double precision real
 c single precision complex
 z double precision complex.

BLACS Combines

Routine name	Results of operation
gamx2d	Entries of result matrix will have the value of the greatest absolute value found in that position.
gamin2d	Entries of result matrix will have the value of the smallest absolute value found in that position.
gsum2d	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```

call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )

```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
top	CHARACTER*1. Communication pattern to use during the combine operation.
m	INTEGER. The number of matrix rows to be combined.
n	INTEGER. The number of matrix columns to be combined.
a	TYPE array (lda, n). Matrix to be compared with to produce the maximum.
lda	INTEGER. The leading dimension of the matrix A, that is, the distance between two successive elements in a matrix row.
rcflag	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.
rdest	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
cdest	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be compared with to produce the minimum.

<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda, n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag, n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> \times <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag, n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> \times <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

```
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be added to produce the sum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
----------	--

Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called.

There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY PROCESS ID()
IF (IAM.EQ. 0) THEN
  SEND TO PROCESS 1
  RECV FROM PROCESS 1
ELSE IF (IAM.EQ. 1) THEN
  SEND TO PROCESS 0
  RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template ?xxyy2d, where the letter in the ? position indicates the data type being sent, xx is replaced to indicate the shape of the matrix, and the yy positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
sd	Send. One process sends to another.
rv	Receive. One process receives from another.

BLACS Point To Point Communication

Routine name	Operation performed
gesd2d	Take the indicated matrix and send it to the destination process.
trsd2d	
gerv2d	Receive a message from the process into the matrix.
trrv2d	

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector x , which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)
IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 1, 0)
    CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
    CALL DGESD2D(5, 1, X, 5, 0, 0)
    CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
m, n, a, lda	Describe the matrix to be sent. See Matrix Shapes for details.

<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

See Also

[Examples of BLACS Routines Usage](#)

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrasd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strasd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call dtrasd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrasd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrasd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m,</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>n, a, lda</i>	
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

```
call zgerv2d( icontext, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontext</i>	INTEGER. Integer handle that indicates the context.
<i>m</i> , <i>n</i> , <i>lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER.
<i>csrc</i>	The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER.
	The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (<i>lda</i> , <i>n</i>) to receive the incoming message into.
----------	---

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

See Also

[Examples of BLACS Routines Usage](#)

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrrv2d( icontext, uplo, diag, m, n, a, lda, rsrc, csrc )
call strrv2d( icontext, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrrv2d( icontext, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrrv2d( icontext, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrrv2d( icontext, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontext</i>	INTEGER. Integer handle that indicates the context.
<i>uplo</i> , <i>diag</i> , <i>m</i> , <i>n</i> , <i>lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER.
<i>csrc</i>	The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER.
	The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (<i>lda</i> , <i>n</i>) to receive the incoming message into.
----------	---

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

BLACS Broadcast Routines

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with SCOPE = 'ALL' must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template ?xxyy2d, where the letter in the ? position indicates the data type being sent, xx is replaced to indicate the shape of the matrix, and the yy positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
bs	Broadcast/send. A process begins the broadcast of data within a scope.
br	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

BLACS Broadcast Routines

Routine name	Operation performed
gebs2d	Start a broadcast along a scope.
trbs2d	
gebr2d	Receive and participate in a broadcast along a scope.
trbr2d

Notice revision #20110804

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix A .

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

<i>a</i>	An array of dimension (<i>lda, n</i>) to receive the incoming message into.
----------	---

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?trbr2d

Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.
----------	--

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

BLACS Support Routines

The support routines perform distinct tasks that can be used for:

[Initialization](#)

[Destruction](#)

[Information Purposes](#)

[Miscellaneous Tasks.](#)

Initialization Routines

This section describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

BLACS Initialization Routines

Routine name	Operation performed
blacs_pinfo	Returns the number of processes available for use.
blacs_setup	Allocates virtual machine and spawns processes.
blacs_get	Gets values that BLACS use for internal defaults.
blacs_set	Sets values that BLACS use for internal defaults.
blacs_gridinit	Assigns available processes into BLACS process grid.
blacs_gridmap	Maps available processes into BLACS process grid.

blacs_pinfo*Returns the number of processes available for use.***Syntax**`call blacs_pinfo(mypnum, nprocs)`**Output Parameters**

<i>mypnum</i>	INTEGER. An integer between 0 and (<i>nprocs</i> - 1) that uniquely identifies each process.
<i>nprocs</i>	INTEGER. The number of processes available for BLACS use.

Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, $nrows * ncols \leq nprocs$. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to `BLACS_SETUP`, this routine returns the correct values for *mypnum* and *nprocs*.

See Also[Examples of BLACS Routines Usage](#)**blacs_setup***Allocates virtual machine and spawns processes.***Syntax**`call blacs_setup(mypnum, nprocs)`**Input Parameters**

<i>nprocs</i>	INTEGER. On the process spawned from the keyboard rather than from <code>pvmspawn</code> , this parameter indicates the number of processes to create when building the virtual machine.
---------------	--

Output Parameters

<i>mypnum</i>	INTEGER. An integer between 0 and (<i>nprocs</i> - 1) that uniquely identifies each process.
---------------	---

<i>nprocs</i>	INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.
---------------	--

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to [blacs_pinfo](#). The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

[blacs_setup](#) is used to allocate the virtual machine and spawn off processes. It reads in a file called `blacs_setup.dat`, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (`PvmTaskDefault`), 4 (`PvmTaskDebug`), 8 (`PvmTaskTrace`), and 12 (`PvmTaskDebug + PvmTaskTrace`). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, `mypnum=0`), and both parameters are output for all processes. So, on PVM systems, the call to [blacs_pinfo](#) informs you that the virtual machine has not been set up, and a call to [blacs_setup](#) then sets up the machine and returns the real values for `mypnum` and *nprocs*.

Note that if the file `blacs_setup.dat` does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

[Examples of BLACS Routines Usage](#)

[blacs_get](#)

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( ictxt, what, val )
```

Input Parameters

ictxt INTEGER. On values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

what INTEGER. Indicates what BLACS internal(s) should be returned in *val*. Present options are:

- *what* = 0 : Handle indicating default system context
- *what* = 1 : The BLACS message ID range
- *what* = 2 : The BLACS debug level the library was compiled with
- *what* = 10 : Handle indicating the system context used to define the BLACS context whose handle is *ictxt*
- *what* = 11 : Number of rings multiring topology is presently using
- *what* = 12 : Number of branches general tree topology is presently using.

Output Parameters

val INTEGER. The value of the BLACS internal.

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into `blacs_gridinit` or `blacs_gridmap`.

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use `blacs_get` to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter `ictxt` is unused.

`blacs_get` returns information on three quantities that are tied to an individual BLACS context, which is passed in as `ictxt`. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for `TOP = 'M'` (multiring broadcast)
- The number of branches for `TOP = 'T'` (general tree broadcast/general tree gather).

[Examples of BLACS Routines Usage](#)

`blacs_set`

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( ictxt, what, val )
```

Input Parameters

<code>ictxt</code>	INTEGER. For values of <code>what</code> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<code>what</code>	INTEGER. Indicates what BLACS internal(s) should be set. Present values are: <ul style="list-style-type: none"> • 1 = The BLACS message ID range • 11 = Number of rings for multiring topology to use • 12 = Number of branches for general tree topology to use.
<code>val</code>	INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <code>what</code> values, as discussed in Description below.

Description

This routine sets the BLACS internal defaults depending on `what` values:

<code>what = 1</code>	Setting the BLACS message ID range. If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to <code>blacs_gridinit</code> or <code>blacs_gridmap</code> . Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter <code>ictxt</code> is ignored, and <code>val</code> is defined as: <code>VAL (input) INTEGER array of dimension (2)</code> <code>VAL(1) : The smallest message ID (also called message type or message tag) the BLACS should use.</code>
-----------------------	--

	VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.
what = 11	Set number of rings for TOP = 'M' (multiring broadcast). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of rings for multiring topology to use.
what = 12	Set number of rings for TOP = 'T' (general tree broadcast/general tree gather). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of branches for general tree topology to use.

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

```
call blacs_gridinit( icontxt, order, nprov, npcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <i>blacs_get</i> to obtain a default system context.
<i>order</i>	CHARACTER*1. Indicates how to map processes to BLACS grid. Options are: <ul style="list-style-type: none">• 'R' : Use row-major natural ordering• 'C' : Use column-major natural ordering• ELSE : Use row-major natural ordering
<i>nprov</i>	INTEGER. Indicates how many process rows the process grid should contain.
<i>npcol</i>	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

<i>icontxt</i>	INTEGER. Integer handle to the created BLACS context.
----------------	---

Description

All BLACS codes must call this routine, or its sister routine *blacs_gridmap*. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine *blacs_setup* should be used to create the virtual machine.

This routine creates a simple `nprov × npcol` process grid. This process grid uses the first `nprov * npcol` processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

`blacs_get`

`blacs_gridmap`

`blacs_setup`

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( icontxt, usermap, ldumap, nprov, npcol )
```

Input Parameters

<code>icontxt</code>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <code>blacs_get</code> to obtain a default system context.
<code>usermap</code>	INTEGER. Array, dimension $(ldumap, npcol)$, indicating the process-to-grid mapping.
<code>ldumap</code>	INTEGER. Leading dimension of the 2D array <code>usermap</code> . $ldumap \geq nprov$.
<code>nprov</code>	INTEGER. Indicates how many process rows the process grid should contain.
<code>npcol</code>	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

<code>icontxt</code>	INTEGER. Integer handle to the created BLACS context.
----------------------	---

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i, j)` holds the process number of the process to be placed in $\{i, j\}$ of the process grid. On most distributed systems, this process number is a machine defined number between $0 \dots nprov-1$. For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a gridmap where the first

`nproc * npcol` processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

`blacs_setup`

Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

BLACS Destruction Routines

Routine name	Operation performed
<code>blacs_freebuff</code>	Frees BLACS buffer.
<code>blacs_gridexit</code>	Frees a BLACS context.
<code>blacs_abort</code>	Aborts all processes.
<code>blacs_exit</code>	Frees all BLACS contexts and releases all allocated memory.

`blacs_freebuff`

Frees BLACS buffer.

Syntax

```
call blacs_freebuff( icontxt, wait )
```

Input Parameters

<code>icontxt</code>	INTEGER. Integer handle that indicates the BLACS context.
<code>wait</code>	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The `wait` parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If `wait = 0`, the BLACS free any buffers that can be freed without waiting. If `wait` is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

blacs_gridexit

Frees a BLACS context.

Syntax

```
call blacs_gridexit( icontxt )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the BLACS context to be freed.

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

blacs_abort

Aborts all processes.

Syntax

```
call blacs_abort( icontxt, errornum )
```

Input Parameters

icontxt INTEGER. Integer handle that indicates the BLACS context to be aborted.

errornum INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

blacs_exit

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

continue INTEGER. Flag indicating whether message passing continues after the BLACS are done. If *continue* is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called;

otherwise, it is not called. Setting `continue` not equal to 0 indicates that explicit PVM send/recvs will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

Informational Routines

This section describes BLACS routines that return information involving the process grid.

BLACS Informational Routines

Routine name	Operation performed
<code>blacs_gridinfo</code>	Returns information on the current grid.
<code>blacs_pnum</code>	Returns the system process number of the process in the process grid.
<code>blacs_pcoord</code>	Returns the row and column coordinates in the process grid.

`blacs_gridinfo`

Returns information on the current grid.

Syntax

```
call blacs_gridinfo( icontxt, nprow, ncol, myrow, mycol )
```

Input Parameters

`icontxt` INTEGER. Integer handle that indicates the context.

Output Parameters

<code>nprow</code>	INTEGER. Number of process rows in the current process grid.
<code>ncol</code>	INTEGER. Number of process columns in the current process grid.
<code>myrow</code>	INTEGER. Row coordinate of the calling process in the process grid.
<code>mycol</code>	INTEGER. Column coordinate of the calling process in the process grid.

Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

[Examples of BLACS Routines Usage](#)

`blacs_pnum`

Returns the system process number of the process in the process grid.

Syntax

```
call blacs_pnum( icontxt, prow, pcol )
```

Input Parameters

`icontxt` INTEGER. Integer handle that indicates the context.

<i>prow</i>	INTEGER. Row coordinate of the process the system process number of which is to be determined.
<i>pcol</i>	INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {PROW, PCOL} in the process grid.

See Also

[Examples of BLACS Routines Usage](#)

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( icontxt, pnum, prow, pcol )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>pnum</i>	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a <i>tid</i> for PVM.

Output Parameters

<i>prow</i>	INTEGER. Row coordinates of the <i>pnum</i> process in the BLACS grid.
<i>pcol</i>	INTEGER. Column coordinates of the <i>pnum</i> process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

Miscellaneous Routines

This section describes `blacs_barrier` routine.

BLACS Informational Routines

Routine name	Operation performed
<code>blacs_barrier</code>	Holds up execution of all processes within the indicated scope until they have all called the routine.

blacs_barrier

Holds up execution of all processes within the indicated scope.

Syntax

```
call blacs_barrier( icontxt, scope )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Parameter that indicates whether a process row (<i>scope</i> ='R'), column ('C'), or entire grid ('A') will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Example. BLACS Usage. Hello World

The following routine takes the available processes, forms them into a process grid, and then has each process check in with the process at {0,0} in the process grid.

Example. BLACS Usage. PARALLEL DOT PRODUCT

This routine does a bone-headed parallel double precision dot product of two vectors. Arguments are input on process {0,0}, and output everywhere else.

```

DOUBLE PRECISION FUNCTION PDDOT( CONTEXT, N, X, Y )
*
* -- BLACS example code --
*
* Written by Clint Whaley 7/26/94
*
* .. Scalar Arguments ..
INTEGER CONTEXT, N
*
* .. Array Arguments ..
DOUBLE PRECISION X(*), Y(*)
*
*
* Purpose
* ======
* PDDOT is a restricted parallel version of the BLAS routine
* DDOT. It assumes that the increment on both vectors is one,
* and that process {0,0} starts out owning the vectors and
*
* has N. It returns the dot product of the two N-length vectors
* X and Y, that is, PDDOT = X' Y.
*
* Arguments
* =====
*
* CONTEXT      (input) INTEGER

Data Fitting Functions

Data Fitting functions in Intel® MKL provide spline-based interpolation capabilities that you can use to approximate functions, function derivatives or integrals, and perform cell search operations.

The Data Fitting component is task based. The task is a data structure or descriptor that holds the parameters related to a specific Data Fitting operation. You can modify the task parameters using the task editing functionality of the library.

For definition of the implemented operations, see [Mathematical Conventions](#).

Data Fitting routines use the following workflow to process a task:

1. Create a task or multiple tasks.
2. Modify the task parameters.
3. Perform a Data Fitting computation.
4. Destroy the task or tasks.

All Data Fitting functions fall into the following categories:

[Task Creation and Initialization Routines](#) - routines that create a new Data Fitting task descriptor and initialize the most common parameters, such as partition of the interpolation interval, values of the vector-valued function, and the parameters describing their structure.

[Task Editors](#) - routines that set or modify parameters in an existing Data Fitting task.

[Computational Routines](#) - routines that perform Data Fitting computations, such as construction of a spline, interpolation, computation of derivatives and integrals, and search.

[Task Destructors](#) - routines that delete Data Fitting task descriptors and deallocate resources.

You can access the Data Fitting routines through the Fortran and C89/C99 language interfaces. You can also use the C89 interface with more recent versions of C/C++, or the Fortran 90 interface with programs written in Fortran 95.

The \${MKL}/include directory of the Intel® MKL contains the following Data Fitting header files:

- C/C++: mkl_df.h
- Fortran: mkl_df.f90 and mkl_df.f77

You can find examples that demonstrate C/C++ and Fortran usage of Data Fitting routines in the \${MKL}/examples/datafittingc and \${MKL}/examples/datafittingf directories, respectively.

Naming Conventions

The Fortran interfaces of the Data Fitting functions are in lowercase, while the names of the types and constants are in uppercase.

The C/C++ interface of the Data Fitting functions, types, and constants are case-sensitive and can be in lowercase, uppercase, and mixed case.

The names of all routines have the following structure:

df[datatype]<base_name>

where

- df is a prefix indicating that the routine belongs to the Data Fitting component of Intel MKL.
- [datatype] field specifies the type of the input and/or output data and can be s (for the single precision real type), d (for the double precision real type), or i (for the integer type). This field is omitted in the names of the routines that are not data type dependent.
- <base_name> field specifies the functionality the routine performs. For example, this field can be NewTask1D, Interpolate1D, or DeleteTask.

Data Types

The Data Fitting component provides routines for processing single and double precision real data types. The results of cell search operations are returned as a generic integer data type.

All Data Fitting routines use the following data type:

Type	Data Object
Fortran: TYPE (DF_TASK)	Pointer to a task
C: DFTaskPtr	

NOTE The actual size of the generic integer type is platform-dependent. Before compiling your application, you need to set an appropriate byte size for integers. For details, see section *Using the ILP64 Interface vs. LP64 Interface* of the Intel® MKL User's Guide.

Mathematical Conventions

This section explains the notation used for Data Fitting function descriptions. Spline notations are based on the terminology and definitions of [deBoor2001]. The definition of Subbotin quadratic splines follows the conventions of [StechSub76].

Mathematical Notation in the Data Fitting Component

Concept	Mathematical Notation
Partition of interpolation interval $[a, b]$, where	$\{x_i\}_{i=1,\dots,n}$, where $a = x_1 < x_2 < \dots < x_n = b$
<ul style="list-style-type: none"> x_i denotes breakpoints. $[x_i, x_{i+1})$ denotes a sub-interval (cell) of size Δx_{i+1-x_i}. 	
Vector-valued function of dimension p being fit	$f(x) = (f_1(x), \dots, f_p(x))$
Piecewise polynomial (PP) function f of order $k+1$	$f(x) := p_i(x)$, if $x \in [x_i, x_{i+1})$, $i = 1, \dots, n-1$ where <ul style="list-style-type: none"> $\{x_i\}_{i=1,\dots,n}$ is a strictly increasing sequence of breakpoints. $p_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k$ is a polynomial of degree k (order $k+1$) over the interval $x \in [x_i, x_{i+1})$.
Function p agrees with function g at the points $\{x_i\}_{i=1,\dots,n}$.	For every point ζ in sequence $\{x_i\}_{i=1,\dots,n}$ that occurs m times, the equality $p^{(i-1)}(\zeta) = g^{(i-1)}(\zeta)$ holds for all $i = 1, \dots, m$, where $p^{(i)}(t)$ is the derivative of the i -th order.
The k -th divided difference of function g at points x_i, \dots, x_{i+k} . This difference is the leading coefficient of the polynomial of order $k+1$ that agrees with g at x_i, \dots, x_{i+k} .	$[x_i, \dots, x_{i+k}] g$ In particular, <ul style="list-style-type: none"> $[x_1] g = g(x_1)$ $[x_1, x_2] g = (g(x_1) - g(x_2)) / (x_1 - x_2)$
A k -order derivative of interpolant $f(x)$ at interpolation site τ .	$f^{(k)}(\tau)$

Interpolants to the Function g at x_1, \dots, x_n and Boundary Conditions

Concept	Mathematical Notation
Linear interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i),$ <p style="margin-left: 20px;">where</p> <ul style="list-style-type: none"> • $x \in [x_i, x_{i+1}]$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = [x_i, x_{i+1}]g$ • $i = 1, \dots, n-1$
Piecewise parabolic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2, x \in [x_i, x_{i+1}]$ <p>Coefficients $c_{1,i}$, $c_{2,i}$, and $c_{3,i}$ depend on the conditions:</p> <ul style="list-style-type: none"> • $P_i(x_i) = g(x_i)$ • $P_i(x_{i+1}) = g(x_{i+1})$ • $P_i((x_{i+1} + x_i) / 2) = v_{i+1}$ <p>where parameter v_{i+1} depends on the interpolant being continuously differentiable:</p> $P_{i-1}^{(1)}(x_i) = P_i^{(1)}(x_i)$
Piecewise parabolic Subbotin interpolant	$P(x) = P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + d_{3,i}((x - t_i)_+)^2,$ <p>where</p> <ul style="list-style-type: none"> • $x \in [t_i, t_{i+1}]$ • $\{t_i\}_{i=1, \dots, n+1}$ is a sequence of knots such that <ul style="list-style-type: none"> • $t_1 = x_1, t_{n+1} = x_n$ • $t_i \in (x_{i-1}, x_i), i = 2, \dots, n$ • $x_+ = f(x) = \begin{cases} 0, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$ <p>Coefficients $c_{1,i}$, $c_{2,i}$, $c_{3,i}$, and $d_{3,i}$ depend on the following conditions:</p> <ul style="list-style-type: none"> • $P_i(x_i) = g(x_i), P_i(x_{i+1}) = g(x_{i+1})$ • $P(x)$ is a continuously differentiable polynomial of the second degree on $[t_i, t_{i+1}], i = 1, \dots, n.$
Piecewise cubic Hermite interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> • $x \in [x_i, x_{i+1}]$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • $s_i = g^{(1)}(x_i)$
Piecewise cubic Bessel interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> • $x \in [x_i, x_{i+1}]$ • $c_{1,i} = g(x_i)$

Concept	Mathematical Notation
	<ul style="list-style-type: none"> • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • $s_i = (\Delta x_i[x_{i-1}, x_i]g + \Delta x_{i-1}[x_i, x_{i+1}]g) / (\Delta x_i + \Delta x_{i+1})$
Piecewise cubic Akima interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> • $x \in [x_i, x_{i+1}]$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • $s_i = (w_{i+1}[x_{i-1}, x_i]g + w_{i-1}[x_i, x_{i+1}]g) / (w_{i+1} + w_{i-1}),$ <p>where</p> $w_i = [x_i, x_{i+1}]g - [x_{i-1}, x_i]g $
Piecewise natural cubic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3,$ <p>where</p> <ul style="list-style-type: none"> • $x \in [x_i, x_{i+1}]$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1, \dots, n-1$ • Parameter s_i depends on the condition that the interpolant is twice continuously differentiable: $P_{i-1}^{(2)}(x_i) = P_i^{(2)}(x_i)$.
Not-a-knot boundary condition.	Parameters s_1 and s_n provide $P_1 = P_2$ and $P_{n-1} = P_n$, so that the first and the last interior breakpoints are inactive.
Free-end boundary condition.	$f''(x_1) = f''(x_n) = 0$
Look-up interpolator for discrete set of points $(x_1, y_1), \dots, (x_n, y_n)$.	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x = x_2 \\ \dots \\ y_n, & \text{if } x = x_n \\ \text{error, otherwise} \end{cases}$

Concept	Mathematical Notation
Step-wise constant continuous right interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x_1 \leq x < x_2 \\ y_2, & \text{if } x_2 \leq x < x_3 \\ \dots \\ y_{n-1}, & \text{if } x_{n-1} \leq x < x_n \\ y_n, & \text{if } x = x_n \end{cases}$
Step-wise constant continuous left interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x_1 < x \leq x_2 \\ y_3, & \text{if } x_2 < x \leq x_3 \\ \dots \\ y_n, & \text{if } x_{n-1} < x \leq x_n \end{cases}$

Data Fitting Usage Model

Consider an algorithm that uses the Data Fitting functions. Typically, such algorithms consist of four steps or stages:

1. Create a task. You can call the Data Fitting function several times to create multiple tasks.

```
status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );
```

2. Modify the task parameters.

```
status = dfdEditPPSpline1D( task, s_order, c_type, bc_type, bc, ic_type, ic,
scoeff, scoeffhint );
```

3. Perform Data Fitting spline-based computations. You may reiterate steps 2-3 as needed.

```
status = dfdInterpolate1D(task, estimate, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell );
```

4. Destroy the task or tasks.

```
status = dfDeleteTask( &task );
```

Data Fitting Usage Examples

The examples below illustrate several operations that you can perform with Data Fitting routines. If you want to run or reuse similar examples, you can get both C and Fortran source code in the `.\examples\datafittingc` and `.\examples\datafittingf` subdirectories of the Intel MKL installation directory.

The following C example demonstrates the construction of a linear spline using Data Fitting routines. The spline approximates a scalar function defined on non-uniform partition. The coefficients of the spline are returned as a one-dimensional array:

C Example of Linear Spline Construction

```
#include "mkl.h"
#define N 500 /* Size of partition, number of breakpoints */
#define SPLINE_ORDER DF_PP_LINEAR /* Linear spline to construct */

int main()
{
```

```

int status;          /* Status of a Data Fitting operation */

/* Parameters describing the partition */
MKL_INT nx;          /* The size of partition x */
double x[N];         /* Partition x */
MKL_INT xhint;        /* Additional information about the structure of breakpoints */

/* Parameters describing the function */
MKL_INT ny;          /* Function dimension */
double y[N];         /* Function values at the breakpoints */
MKL_INT yhint;        /* Additional information about the function */

/* Parameters describing the spline */
MKL_INT s_order;      /* Spline order */
MKL_INT s_type;        /* Spline type */
MKL_INT ic_type;       /* Type of internal conditions */
MKL_INT* ic;           /* Array of internal conditions */
MKL_INT bc_type;       /* Type of boundary conditions */
MKL_INT* bc;           /* Array of boundary conditions */

double scoeff[(N-1)* ORDER];    /* Array of spline coefficients */
MKL_INT scoeffhint;            /* Additional information about the coefficients */

/* Initialize the partition */
nx = N;
/* Set values of partition x */
...
xhint = DF_NO_HINT;    /* No additional information about the function is provided.
                           By default, the partition is non-uniform. */
/* Initialize the function */
ny = 1;                /* The function is scalar. */

/* Set function values */
...
yhint = DF_NO_HINT;    /* No additional information about the function is provided. */

/* Create a Data Fitting task */
status = dfdNewTaskID( &task, nx, x, xhint, ny, y, yhint );

/* Check the Data Fitting operation status */
...

/* Initialize spline parameters */
s_order = DF_PP_LINEAR;    /* Spline is of the second order. */
s_type = DF_PP_DEFAULT;    /* Spline is of the default type. */

/* Define internal conditions for linear spline construction (none in this example) */
ic_type = DF_NO_IC;
ic = NULL;

/* Define boundary conditions for linear spline construction (none in this example) */
bc_type = DF_NO_BC;
bc = NULL;
scoeffhint = DF_NO_HINT;    /* No additional information about the spline. */

/* Set spline parameters in the Data Fitting task */
status = dfdEditPPSpline1D( task, s_order, s_type, bc_type, ic_type,
                            ic, scoeff, scoeffhint );

/* Check the Data Fitting operation status */
...

/* Use a standard computation method to construct a linear spline: */
/* Pi(x) = c1,i+c2,i(x-xi), i=0,..., N-2 */
/* The library packs spline coefficients to array scoeff. */
/* scoeff[2*i+0]=c1,i and scoeff[2*i+1]=c2,i, i=0,..., N-2 */
status = dfdConstruct1D( task, DF_PP_SPLINE, DF_METHOD_STD );

/* Check the Data Fitting operation status */
...

```

```

/* Process spline coefficients */
...
/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task ) ;

/* Check the Data Fitting operation status */
...
return 0 ;
}

```

The following C example demonstrates cubic spline-based interpolation using Data Fitting routines. In this example, a scalar function defined on non-uniform partition is approximated by Bessel cubic spline using not-a-knot boundary conditions. Once the spline is constructed, you can use the spline to compute spline values at the given sites. Computation results are packed by the Data Fitting routine in row-major format.

C Example of Cubic Spline-Based Interpolation

```

#include "mkl.h"

#define NX 100          /* Size of partition, number of breakpoints */
#define NSITE 1000       /* Number of interpolation sites */
#define SPLINE_ORDER DF_PP_CUBIC /* A cubic spline to construct */

int main()
{
    int status;           /* Status of a Data Fitting operation */
    DFTaskPtr task;      /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;          /* The size of partition x */
    double x[N];          /* Partition x */
    MKL_INT xhint;        /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny;          /* Function dimension */
    double y[N];          /* Function values at the breakpoints */
    MKL_INT yhint;        /* Additional information about the function */

    /* Parameters describing the spline */
    MKL_INT s_order;      /* Spline order */
    MKL_INT s_type;        /* Spline type */
    MKL_INT ic_type;      /* Type of internal conditions */
    MKL_INT* ic;           /* Array of internal conditions */
    MKL_INT bc_type;      /* Type of boundary conditions */
    MKL_INT* bc;           /* Array of boundary conditions */

    double scoeff[(N-1)* ORDER]; /* Array of spline coefficients */
    MKL_INT scoeffhint;        /* Additional information about the coefficients */

    /* Parameters describing interpolation computations */
    MKL_INT nsite;          /* Number of interpolation sites */
    double site[NSITE];      /* Array of interpolation sites */
    MKL_INT sitehint;        /* Additional information about the structure of
                                interpolation sites */

    MKL_INT ndorder, dorder; /* Parameters defining the type of interpolation */

    double* datahint;        /* Additional information on partition and interpolation sites */

    double r[NSITE];          /* Array of interpolation results */

...
/* Process cell indices */
...
/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task );
/* Check Data Fitting operation status */
...
return 0;
}

```

Task Status and Error Reporting

The Data Fitting routines report a task status through integer values. Negative status values indicate errors, while positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names predefined in the respective header files. For the C/C++ interface, these names are defined as macros via the `#define` statements. For the Fortran interface, the names are defined as integer constants via the `PARAMETER` operators.

If no error occurred, the function returns the `DF_STATUS_OK` code defined as zero:

C/C++:	<code>#define DF_STATUS_OK 0</code>
F90/F95:	<code>INTEGER, PARAMETER::DF_STATUS_OK = 0</code>

In case of an error, the function returns a non-zero error code that specifies the origin of the failure. Header files for both C/C++ and Fortran languages define the following status codes:

Status Codes in the Data Fitting Component

Status Code	Description
Common Status Codes	
<code>DF_STATUS_OK</code>	Operation completed successfully.
<code>DF_ERROR_NULL_TASK</code>	Data Fitting task is a <code>NULL</code> pointer.
<code>DF_ERROR_MEM_FAILURE</code>	Memory allocation failure.
<code>DF_ERROR_METHOD_NOT_SUPPORTED</code>	Requested method is not supported.
<code>DF_ERROR_COMP_TYPE_NOT_SUPPORTED</code>	Requested computation type is not supported.

Data Fitting Task Creation and Initialization, and Generic Editing Operations

<code>DF_ERROR_BAD_NX</code>	Invalid number of breakpoints.
<code>DF_ERROR_BAD_X</code>	Array of breakpoints is invalid.
<code>DF_ERROR_BAD_X_HINT</code>	Invalid hint describing the structure of the partition.
<code>DF_ERROR_BAD_NY</code>	Invalid dimension of vector-valued function y .
<code>DF_ERROR_BAD_Y</code>	Array of function values is invalid.
<code>DF_ERROR_BAD_Y_HINT</code>	Invalid flag describing the structure of function y

Status Code	Description
Data Fitting Task-Specific Editing Operations	
DF_ERROR_BAD_SPLINE_ORDER	Invalid spline order.
DF_ERROR_BAD_SPLINE_TYPE	Invalid spline type.
DF_ERROR_BAD_IC_TYPE	Type of internal conditions used for spline construction is invalid.
DF_ERROR_BAD_IC	Array of internal conditions for spline construction is not defined.
DF_ERROR_BAD_BC_TYPE	Type of boundary conditions used in spline construction is invalid.
DF_ERROR_BAD_BC	Array of boundary conditions for spline construction is not defined.
DF_ERROR_BAD_PP_COEFF	Array of piecewise polynomial spline coefficients is not defined.
DF_ERROR_BAD_PP_COEFF_HINT	Invalid flag describing the structure of the piecewise polynomial spline coefficients.
DF_ERROR_BAD_PERIODIC_VAL	Function values at the endpoints of the interpolation interval are not equal as required in periodic boundary conditions.
DF_ERROR_BAD_DATA_ATTR	Invalid attribute of the pointer to be set or modified in Data Fitting task descriptor with the <code>df?editidxptr</code> task editor.
DF_ERROR_BAD_DATA_IDX	Index of the pointer to be set or modified in the Data Fitting task descriptor with the <code>df?editidxptr</code> task editor is out of the pre-defined range.
Data Fitting Computation Operations	
DF_ERROR_BAD_NSITE	Invalid number of interpolation sites.
DF_ERROR_BAD_SITE	Array of interpolation sites is not defined.
DF_ERROR_BAD_SITE_HINT	Invalid flag describing the structure of interpolation sites.
DF_ERROR_BAD_NDORDER	Invalid size of the array defining derivative orders to be computed at interpolation sites.
DF_ERROR_BAD_DORDER	Array defining derivative orders to be computed at interpolation sites is not defined.
DF_ERROR_BAD_DATA_HINT	Invalid flag providing additional information about partition or interpolation sites.
DF_ERROR_BAD_INTERP	Array of spline-based interpolation results is not defined.
DF_ERROR_BAD_INTERP_HINT	Invalid flag defining the structure of spline-based interpolation results.
DF_ERROR_BAD_CELL_IDX	Array of indices of partition cells containing interpolation sites is not defined.

Status Code	Description
DF_ERROR_BAD_NLIM	Invalid size of arrays containing integration limits.
DF_ERROR_BAD_LLIM	Array of the left-side integration limits is not defined.
DF_ERROR_BAD_RLIM	Array of the right-side integration limits is not defined.
DF_ERROR_BAD_INTEGR	Array of spline-based integration results is not defined.
DF_ERROR_BAD_INTEGR_HINT	Invalid flag providing the structure of the array of spline-based integration results.
DF_ERROR_BAD_LOOKUP_INTERP_SITE	Bad site provided for interpolation with look-up interpolator.

NOTE The routine that estimates piecewise polynomial cubic spline coefficients can return internal error codes related to the specifics of the implementation. Such error codes indicate invalid input data or other issues unrelated to Data Fitting routines.

Task Creation and Initialization Routines

Task creation and initialization routines are functions used to create a new task descriptor and initialize its parameters. The Data Fitting component provides the `df?newtask1d` routine that creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

`df?newtask1d`

Creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

Syntax

Fortran:

```
status = dfsnewtask1d(task, nx, x, xhint, ny, y, yhint)
status = dfdnewtask1d(task, nx, x, xhint, ny, y, yhint)
```

C:

```
status = dfsNewTask1D(&task, nx, x, xhint, ny, y, yhint)
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>nx</code>	Fortran: INTEGER C: <code>MKL_INT*</code>	Number of breakpoints representing partition of interpolation interval $[a, b]$.

Name	Type	Description
<i>x</i>	Fortran: REAL (KIND=4) DIMENSION(*) for dfsnewtask1d REAL (KIND=8) DIMENSION(*) for dfdnewtask1d C: float* for dfsNewTask1D double* for dfdNewTask1D	<p>One-dimensional array containing the sorted breakpoints from interpolation interval $[a, b]$. The structure of the array is defined by parameter <i>xhint</i>:</p> <ul style="list-style-type: none"> If partition is non-uniform or quasi-uniform, the array should contain <i>nx</i> ordered values. If partition is uniform, the array should contain two entries that represent endpoints of interpolation interval $[a, b]$.
<i>xhint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of partition <i>x</i> . For the list of possible values of <i>xhint</i> , see table " Hint Values for Partition <i>x</i> ". If you set the flag to the DF_NO_HINT value, the library interprets the partition as non-uniform.
<i>ny</i>	Fortran: INTEGER C: MKL_INT	Dimension of vector-valued function <i>y</i> .
<i>y</i>	Fortran: REAL (KIND=4) DIMENSION(*) for dfsnewtask1d REAL (KIND=8) DIMENSION(*) for dfdnewtask1d C: float* for dfsNewTask double* for dfdNewTask	<p>Vector-valued function <i>y</i>, array of size <i>nx*ny</i>.</p> <p>The storage format of function values in the array is defined by the value of flag <i>yhint</i>.</p>
<i>yhint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of array <i>y</i> . Valid hint values are listed in table " Hint Values for Vector-Valued Function <i>y</i> ". If you set the flag to the DF_NO_HINT value, the library assumes that all <i>ny</i> coordinates of the vector-valued function <i>y</i> are provided and stored in row-major format.

Output Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE (DF_TASK) C: DFTaskPtr	Descriptor of the task.
<i>status</i>	Fortran: INTEGER C: int	<p>Status of the routine:</p> <ul style="list-style-type: none"> DF_STATUS_OK if the task is created successfully. Non-zero error code if the task creation failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?newtask1d` routine creates and initializes a new Data Fitting task descriptor with user-specified parameters for a one-dimensional Data Fitting task. The *x* and *nx* parameters representing the partition of interpolation interval $[a, b]$ are mandatory. If you provide invalid values for these parameters, such as a NULL pointer *x* or the number of breakpoints smaller than two, the routine does not create the Data Fitting task and returns an error code.

If you provide a vector-valued function y , make sure that the function dimension ny and the array of function values y are both valid. If any of these parameters are invalid, the routine does not create the Data Fitting task and returns an error code.

If you store coordinates of the vector-valued function y in non-contiguous memory locations, you can set the $yhint$ flag to `DF_1ST_COORDINATE`, and pass only the first coordinate of the function into the task creation routine. After successful creation of the Data Fitting task, you can pass the remaining coordinates using the `df?editidxptr` task editor.

If the routine fails to create the task descriptor, it returns a `NULL` task pointer.

The routine supports the following hint values for partition x :

Hint Values for Partition x

Value	Description
<code>DF_NON_UNIFORM_PARTITION</code>	Partition is non-uniform.
<code>DF_QUASI_UNIFORM_PARTITION</code>	Partition is quasi-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition is uniform.
<code>DF_NO_HINT</code>	No hint is provided. By default, partition is interpreted as non-uniform.

The routine supports the following hint values for the vector-valued function:

Hint Values for Vector-Valued Function y

Value	Description
<code>DF_MATRIX_STORAGE_ROWS</code>	Data is stored in row-major format according to C conventions.
<code>DF_MATRIX_STORAGE_COLS</code>	Data is stored in column-major format according to Fortran conventions.
<code>DF_1ST_COORDINATE</code>	The first coordinate of vector-valued data is provided.
<code>DF_NO_HINT</code>	No hint is provided. By default, the coordinates of vector-valued function y are provided and stored in row-major format.

Task Editors

Task editors initialize or change the predefined Data Fitting task parameters. You can use task editors to initialize or modify pointers to arrays or parameter values.

Task editors can be task-specific and generic. Task-specific editors can modify more than one parameter related to a specific task. Generic editors modify a single parameter at a time.

The Data Fitting component of the Intel MKL provides the following task editors:

Data Fitting Task Editors

Editor	Description	Type
<code>df?editppsplinel1d</code>	Changes parameters of the piecewise polynomial spline.	Task-specific
<code>df?editptr</code>	Changes a pointer in the task descriptor.	Generic
<code>dfieditval</code>	Changes a value in the task descriptor.	Generic

Editor	Description	Type
<code>df?editidxptr</code>	Changes a coordinate of data represented in matrix format. For example, a vector-valued function or spline coefficients.	Generic

df?editppspline1d

Modifies parameters representing a spline in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfreditppspline1d(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

```
status = dfreditppspline1d(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

C:

```
status = dfsEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

```
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
<code>s_order</code>	Fortran: INTEGER C: MKL_INT	Spline order. The parameter takes one of the values described in table " Spline Orders Supported by Data Fitting Functions ".
<code>s_type</code>	Fortran: INTEGER C: MKL_INT	Spline type. The parameter takes one of the values described in table " Spline Types Supported by Data Fitting Functions ".
<code>bc_type</code>	Fortran: INTEGER C: MKL_INT	Type of boundary conditions. The parameter takes one of the values described in table " Boundary Conditions Supported by Data Fitting Functions ".
<code>bc</code>	Fortran: REAL(KIND=4) DIMENSION(*) for dfseditppspline1d	Pointer to boundary conditions. The size of the array is defined by the value of parameter <code>bc_type</code> : <ul style="list-style-type: none"> If you set free-end or not-a-knot boundary conditions, pass the NULL pointer to this parameter.

Name	Type	Description
	REAL(KIND=8) DIMENSION(*) for dfdeditppspline1D C: float* for dfsEditPPSpline1D double* for dfdEditPPSpline1D	<ul style="list-style-type: none"> If you combine boundary conditions at the endpoints of the interpolation interval, pass an array of two elements. If you set a boundary condition for the default quadratic spline or a periodic condition for Hermite or the default cubic spline, pass an array of one element.
<i>ic_type</i>	Fortran: INTEGER C: MKL_INT	Type of internal conditions. The parameter takes one of the values described in table " Internal Conditions Supported by Data Fitting Functions ".
<i>ic</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfseditppspline1D REAL(KIND=8) DIMENSION(*) for dfdeditppspline1D C: float* for dfsEditPPSpline1D double* for dfdEditPPSpline1D	<p>A non-NULL pointer to the array of internal conditions. The size of the array is defined by the value of parameter <i>ic_type</i>:</p> <ul style="list-style-type: none"> If you set first derivatives or second derivatives internal conditions (<i>ic_type</i>=DF_IC_1ST_DER or <i>ic_type</i>=DF_IC_2ND_DER), pass an array of <i>n</i>-1 derivative values at the internal points of the interpolation interval. If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is non-uniform, pass an array of <i>n</i>+1 elements. If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is uniform, pass an array of four elements.
<i>scoeff</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfseditppspline1D REAL(KIND=8) DIMENSION(*) for dfdeditppspline1D C: float* for dfsEditPPSpline1D double* for dfdEditPPSpline1D	Spline coefficients. An array of size <i>s_order</i> *(<i>nx</i> -1). The storage format of the coefficients in the array is defined by the value of flag <i>scoeffhint</i> .
<i>scoeffhint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of the array of spline coefficients. For valid hint values, see table " Hint Values for Spline Coefficients ". The library stores the coefficients in row-major format. The default value is DF_NO_HINT.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> DF_STATUS_OK if the routine execution completed successfully.

Name	Type	Description
		<ul style="list-style-type: none"> Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The editor modifies parameters that describe the order, type, boundary conditions, internal conditions, and coefficients of a spline. The spline order definition is provided in the "[Mathematical Conventions](#)" section. You can set the spline order to any value supported by Data Fitting functions. The table below lists the available values:

Spline Orders Supported by the Data Fitting Functions

Order	Description
DF_PP_STD	Artificial value. Use this value for look-up and step-wise constant interpolants only.
DF_PP_LINEAR	Piecewise polynomial spline of the second order (linear spline).
DF_PP_QUADRATIC	Piecewise polynomial spline of the third order (quadratic spline).
DF_PP_CUBIC	Piecewise polynomial spline of the fourth order (cubic spline).

To perform computations with a spline not supported by Data Fitting routines, set the parameter defining the spline order and pass the spline coefficients to the library in the supported format. For format description, see figure "[Row-major Coefficient Storage Format](#)".

The table below lists the supported spline types:

Spline Types Supported by Data Fitting Functions

Type	Description
DF_PP_DEFAULT	The default spline type. You can use this type with linear, quadratic, or user-defined splines.
DF_PP_SUBBOTIN	Quadratic splines based on Subbotin algorithm, [StechSub76].
DF_PP_NATURAL	Natural cubic spline.
DF_PP_HERMITE	Hermite cubic spline.
DF_PP_BESSEL	Bessel cubic spline.
DF_PP_AKIMA	Akima cubic spline.
DF_LOOKUP_INTERPOLANT	Look-up interpolant.
DF_CR_STEPWISE_CONST_INTERPOLANT	Continuous right step-wise constant interpolant.
DF_CL_STEPWISE_CONST_INTERPOLANT	Continuous left step-wise constant interpolant.

If you perform computations with look-up or step-wise constant interpolants, set the spline order to the DF_PP_STD value.

Construction of specific splines may require boundary or internal conditions. To compute coefficients of such splines, you should pass boundary or internal conditions to the library by specifying the type of the conditions and providing the necessary values. For splines that do not require additional conditions, such as linear splines, set condition types to `DF_NO_BC` and `DF_NO_IC`, and pass `NULL` pointers to the conditions. The table below defines the supported boundary conditions:

Boundary Conditions Supported by Data Fitting Functions

Boundary Condition	Description	Spline
<code>DF_BC_NOT_A_KNOT</code>	Not-a-knot boundary conditions.	Akima, Bessel, Hermite, natural cubic
<code>DF_BC_FREE_END</code>	Free-end boundary conditions.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
<code>DF_BC_1ST_LEFT_DER</code>	The first derivative at the left endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
<code>DF_BC_1ST_RIGHT_DER</code>	The first derivative at the right endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
<code>DF_BC_2ST_LEFT_DER</code>	The second derivative at the left endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
<code>DF_BC_2ND_RIGHT_DER</code>	The second derivative at the right endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
<code>DF_BC_PERIODIC</code>	Periodic boundary conditions.	Linear, all cubic splines
<code>DF_BC_Q_VAL</code>	Function value at point $(x_0 + x_1)/2$	Default quadratic

You can combine the values of boundary conditions with a bitwise `OR` operation. This permits you to pass combinations of first and second derivatives at the endpoints of the interpolation interval into the library. To pass a first derivative at the left endpoint and a second derivative at the right endpoint, set the boundary conditions to `DF_BC_1ST_LEFT_DER OR DF_BC_2ND_RIGHT_DER`.

You should pass the combined boundary conditions as an array of two elements. The first entry of the array contains the value of the boundary condition for the left endpoint of the interpolation interval, and the second entry - for the right endpoint. Pass other boundary conditions as arrays of one element.

For the conditions defined as a combination of valid values, the library applies the following rules to identify the boundary condition type:

- If not required for spline construction, the value of boundary conditions is ignored.
- Not-a-knot condition has the highest priority. If set, other boundary conditions are ignored.
- Free-end condition has the second priority after the not-a-knot condition. If set, other boundary conditions are ignored.
- Periodic boundary condition has the next priority after the free-end condition.
- The first derivative has higher priority than the second derivative at the right and left endpoints.

If you set the periodic boundary condition, make sure that function values at the endpoints of the interpolation interval are identical. Otherwise, the library returns an error code. The table below specifies the values to be provided for each type of spline if the periodic boundary condition is set.

Boundary Requirements for Periodic Conditions

Spline Type	Periodic Boundary Condition Support	Boundary Value
Linear	Yes	Not required
Default quadratic	No	
Subbotin quadratic	No	
Natural cubic	Yes	Not required
Bessel	Yes	Not required
Akima	Yes	Not required
Hermite cubic	Yes	First derivative
Default cubic	Yes	Second derivative

Internal conditions supported in the Data Fitting domain that you can use for the `ic_type` parameter are the following:

Internal Conditions Supported by Data Fitting Functions

Internal Condition	Description	Spline
<code>DF_IC_1ST_DER</code>	Array of first derivatives of size $n-2$, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Hermite cubic
<code>DF_IC_2ND_DER</code>	Array of second derivatives of size $n-2$, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Default cubic
<code>DF_IC_Q_KNOT</code>	Knot array of size $n+1$, where n is the number of breakpoints.	Subbotin quadratic

To construct a Subbotin quadratic spline, you have three options to get the array of knots in the library:

- If you do not provide the knots, the library uses the default values of knots $t = \{t_i\}$, $i = 0, \dots, n$ according to the rule:

$$t_0 = x_0, t_n = x_{n-1}, t_i = (x_i + x_{i-1})/2, i = 1, \dots, n - 1.$$
- If you provide the knots in an array of size $n + 1$, the knots form a non-uniform partition. Make sure that the knot values you provide meet the following conditions:

$$t_0 = x_0, t_n = x_{n-1}, t_i \in (x_{i-1}, x_i), i = 1, \dots, n - 1.$$
- If you provide the knots in an array of size 4, the knots form a uniform partition

$$t_0 = x_0, t_1 = l, t_2 = r, t_3 = x_{n-1}, \text{ where } l \in (x_0, x_1) \text{ and } r \in (x_{n-2}, x_{n-1}).$$

In this case, you need to set the value of the `ic_type` parameter holding the type of internal conditions to `DF_IC_Q_KNOT` OR `DF_UNIFORM_PARTITION`.

NOTE Since the partition is uniform, perform an OR operation with the `DF_UNIFORM_PARTITION` partition hint value described in [Table Hint Values for Partition x](#).

For computations based on look-up and step-wise constant interpolants, you can avoid calling the `df?editppsplinel1d` editor and directly call one of the routines for spline-based computation of spline values, derivatives, or integrals. For example, you can call the `df?constructl1d` routine to construct the required spline with the given attributes, such as order or type.

The memory location of the spline coefficients is defined by the `scoeff` parameter. Make sure that the size of the array is sufficient to hold `s_order * (nx-1)` values.

The `df?editppsplinel1d` routine supports the following hint values for spline coefficients:

Hint Values for Spline Coefficients

Order	Description
<code>DF_1ST_COORDINATE</code>	The first coordinate of vector-valued data is provided.
<code>DF_NO_HINT</code>	No hint is provided. By default, all sets of spline coefficients are stored in row-major format.

The coefficients for all coordinates of the vector-valued function are packed in memory one by one in successive order, from function y_1 to function y_n .

Within each coordinate, the library stores the coefficients as an array, in row-major format:

$$c_{1,0}, c_{1,1}, \dots, c_{1,k}, c_{2,0}, c_{2,1}, \dots, c_{2,k}, \dots, c_{n-1,0}, c_{n-1,1}, \dots, c_{n-1,k}$$

Mapping of the coefficients to storage in the `scoeff` array is described below, where $c_{i,j}$ is the j th coefficient of the function

$$P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k$$

See [Mathematical Conventions](#) for more details on nomenclature and interpolants.

Row-major Coefficient Storage Format

$$\begin{aligned} P_1(x) &= \overrightarrow{c}_{1,0} + \overrightarrow{c}_{1,1}(x - x_1) + \overrightarrow{\dots} + \overrightarrow{c}_{1,k} \overbrace{(x - x_1)^k} \\ P_2(x) &= \overrightarrow{c}_{2,0} + \overrightarrow{c}_{2,1}(x - x_2) + \overrightarrow{\dots} + \overrightarrow{c}_{2,k} \overbrace{(x - x_2)^k} \\ &\vdots && \vdots \\ P_{n-1}(x) &= \overrightarrow{c}_{n-1,0} + \overrightarrow{c}_{n-1,1}(x - x_{n-1}) + \overrightarrow{\dots} + \overrightarrow{c}_{n-1,k} \overbrace{(x - x_{n-1})^k} \end{aligned}$$

If you store splines corresponding to different coordinates of the vector-valued function at non-contiguous memory locations, do the following:

1. Set the `scoeffhint` flag to `DF_1ST_COORDINATE` and provide the spline for the first coordinate.
2. Pass the spline coefficients for the remaining coordinates into the Data Fitting task using the `df?editidxptr` task editor.

Using the `df?editpppline1d` task editor, you can provide to the Data Fitting task an already constructed spline that you want to use in computations. To ensure correct interpretation of the memory content, you should set the following parameters:

- Spline order and type, if appropriate. If the spline is not supported by the library, set the `s_type` parameter to `DF_PP_DEFAULT`.
- Pointer to the array of spline coefficients in row-major format.
- The `scoeffhint` parameter describing the structure of the array:
 - Set the `scoeffhint` flag to the `DF_1ST_COORDINATE` value to pass spline coefficients stored at different memory locations. In this case, you can set the parameters that describe boundary and internal conditions to zero.
 - Use the default value `DF_NO_HINT` for all other cases.

After you provide the spline to the Data Fitting task, you can run computations that use this spline.

df?editptr

Modifies a pointer to an array held in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfreditptr(task, ptr_type, ptr)
status = dfreditptr(task, ptr_type, ptr)
status = dfreditptr(task, ptr_type, ptr)
```

C:

```
status = dfsEditPtr(task, ptr_type, ptr)
status = dfdEditPtr(task, ptr_type, ptr)
status = dfiEditPtr(task, ptr_type, ptr)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
<code>ptr_type</code>	Fortran: INTEGER C: MKL_INT	The parameter to change. For details, see the <i>Pointer Type</i> column in table " Pointers Supported by the df?editptr Task Editor ".
<code>ptr</code>	Fortran: REAL(KIND=4) DIMENSION(*) for dfreditptr REAL(KIND=8) DIMENSION(*) for dfreditptr	New pointer. For details, see the <i>Purpose</i> column in table " Pointers Supported by the df?editptr Task Editor ".

Name	Type	Description
	INTEGER DIMENSION(*) for dfieditptr	
C:	float* for dfsEditPtr	
	double* for dfdEditPtr	
	MKL_INT* for dfiEditPtr	

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER	Status of the routine:
C:	int	<ul style="list-style-type: none"> DF_STATUS_OK if the routine execution completed successfully. Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?editptr` editor replaces the pointer of type `ptr_type` stored in a Data Fitting task descriptor with a new pointer `ptr`. The table below describes types of pointers supported by the editor:

Pointers Supported by the `df?editptr` Task Editor

Pointer Type	Purpose
DF_X	Partition <code>x</code> of the interpolation interval
DF_Y	Vector-valued function <code>y</code>
DF_IC	Internal conditions for spline construction. For details, see table "Internal Conditions Supported by Data Fitting Functions" .
DF_BC	Boundary conditions for spline construction. For details, see table "Boundary Conditions Supported by Data Fitting Functions" .
DF_PP_SCOEFF	Spline coefficients

You can use `df?editptr` to modify different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory. Use the `df?editidxptr` editor if you need to modify pointers to coordinates of the vector-valued function or spline coefficients stored at non-contiguous memory locations.

If you pass a `NULL` pointer to the `df?editptr` task editor, the task remains unchanged and the routine returns an error code. For the predefined error codes, please see ["Task Status and Error Reporting"](#).

dfieditval

Modifies a parameter value in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfieditval(task, val_type, val)
```

C:

```
status = dfiEditVal(task, val_type, val)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
val_type	Fortran: INTEGER C: MKL_INT	The parameter to change. See table " Parameters Supported by the dfieditval Task Editor ".
val	Fortran: INTEGER C: MKL_INT	A new parameter value. See table " Parameters Supported by the dfieditval Task Editor ".

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The dfieditval task editor replaces the parameter of type `val_type` stored in a Data Fitting task descriptor with a new value `val`. The table below describes valid types of parameter `val_type` supported by the editor:

[Parameters Supported by the dfieditval Task Editor](#)

Parameter	Purpose
DF_NX	Number of breakpoints
DF_XHINT	A flag describing the structure of partition. See table " Hint Values for Partition x " for the list of available values.
DF_NY	Dimension of the vector-valued function
DF_YHINT	A flag describing the structure of the vector-valued function. See table " Hint Values for Vector Function y " for the list of available values.
DF_SPLINE_ORDER	Spline order. See table " Spline Orders Supported by Data Fitting Functions " for the list of available values.
DF_SPLINE_TYPE	Spline type. See table " Spline Types Supported by Data Fitting Functions " for the list of available values.

Parameter	Purpose
DF_BC_TYPE	Type of boundary conditions used in spline construction. See table " Boundary Conditions Supported by Data Fitting Functions " for the list of available values.
DF_IC_TYPE	Type of internal conditions used in spline construction. See table " Internal Conditions Supported by Data Fitting Functions " for the list of available values.
DF_PP_COEFF_HINT	A flag describing the structure of spline coefficients. See table " Hint Values for Spline Coefficients " for the list of available values.

If you pass a zero value for the parameter describing the size of the arrays that hold coefficients for a partition, a vector-valued function, or a spline, the parameter held in the Data fitting task remains unchanged and the routine returns an error code. For the predefined error codes, see "[Task Status and Error Reporting](#)".

If you modify the parameter describing dimensions of the arrays that hold the vector-valued function or spline coefficients in contiguous memory, you should call the `df?editptr` task editor with the corresponding pointers to the vector-valued function or spline coefficients even when this pointer remains unchanged. Call the `df?editidxptr` editor if those arrays are stored in non-contiguous memory locations.

df?editidxptr

Modifies a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

Fortran:

```
status = dfreditidxptr(task, type, idx, ptr)
status = dfreditidxptr(task, type, idx, ptr)
```

C:

```
status = dfsEditIdxPtr(task, type, idx, ptr)
status = dfdEditIdxPtr(task, type, idx, ptr)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE (DF_TASK) C: DFTaskPtr	Descriptor of the task.
<i>type</i>	Fortran: INTEGER C: MKL_INT	Type of the data to be modified. The parameter takes one of the values described in " Data Attributes Supported by the df?editidxptr Task Editor ".
<i>idx</i>	Fortran: INTEGER	Index of the coordinate whose pointer is to be modified.

Name	Type	Description
	C: MKL_INT	
<i>ptr</i>	Fortran: REAL (KIND=4) DIMENSION(*) for dfreditidxptr	Pointer to the data that holds values of coordinate <i>idx</i> . For details, see table " Data Attributes Supported by the df?editidxptr Task Editor ".
	REAL (KIND=8) DIMENSION(*) for dfreditidxptr	
	C: float* for dfsEditIdxPtr double* for dfdEditIdxPtr	

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER	Status of the routine:
	C: int	<ul style="list-style-type: none"> DF_STATUS_OK if the routine execution completed successfully. Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine modifies a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the editor if you need to pass into a Data Fitting task or modify the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations.

Before calling this editor, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?editppsplinel1d` editor.

[Data Attributes Supported by the df?editidxptr Task Editor](#)

Data Attribute	Description
DF_Y	Vector-valued function <i>y</i>
DF_PP_SCOEFF	Piecewise polynomial spline coefficients

When using `df?editidxptr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension *ny* of the vector-valued function.
- You pass a NULL pointer to the editor. In this case, the task remains unchanged.

The code example below demonstrates how to use the editor for providing values of a vector-valued function stored in two non-contiguous arrays:

```
#define NX 1000 /* number of break points */
#define NY 2      /* dimension of vector-valued function */
int main()
{
    DFTaskPtr task;
    double x[NX];
    double y1[NX], y2[NX]; /* vector-valued function is stored as two arrays */
    /* Provide first coordinate of two-dimensional function y into creation routine */
    status = dfdNewTask1D( &task, NX, x, DF_NON_UNIFORM_PARTITION, NY, y1,
```

```

        DF_1ST_COORDINATE );
/* Provide second coordinate of two-dimensional function */
status = dfdEditIdxPtr(task, DF_Y, 1, y2 );
...
}

```

Computational Routines

Data Fitting computational routines are functions used to perform spline-based computations, such as:

- spline construction
- computation of values, derivatives, and integrals of the predefined order
- cell search

Once you create a Data Fitting task and initialize the required parameters, you can call computational routines as many times as necessary.

The table below lists the available computational routines:

Data Fitting Computational Routines

Routine	Description
df?construct1d	Constructs a spline for a one-dimensional Data Fitting task.
df?interpolate1d	Computes spline values and derivatives.
df?interpolateex1d	Computes spline values and derivatives by calling user-provided interpolants.
df?integrate1d	Computes spline-based integrals.
df?integrateex1d	Computes spline-based integrals by calling user-provided integrators.
df?searchcells1d	Finds indices of cells containing interpolation sites.
df?searchcellsex1d	Finds indices of cells containing interpolation sites by calling user-provided cell searchers.

If a Data Fitting computation completes successfully, the computational routines return the `DF_STATUS_OK` code. If an error occurs, the routines return an error code specifying the origin of the failure. Some possible errors are the following:

- The task pointer is `NULL`.
- Memory allocation failed.
- The computation failed for another reason.

For the list of available status codes, see "[Task Status and Error Reporting](#)".

NOTE Data Fitting computational routines do not control errors for floating-point conditions, such as overflow, gradual underflow, or operations with Not a Number (NaN) values.

df?construct1d

Constructs a spline of the given type.

Syntax

Fortran:

```
status = dfsconstruct1d(task, s_format, method)
```

```
status = dfdconstruct1d(task, s_format, method)
```

C:

```
status = dfsConstruct1D(task, s_format, method)
status = dfdConstruct1D(task, s_format, method)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
s_format	Fortran: INTEGER C: MKL_INT	Spline format. The supported value is DF_PP_SPLINE.
method	Fortran: INTEGER C: MKL_INT	Construction method. The supported value is DF_METHOD_STD.

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

Before calling `df?construct1d`, you need to create and initialize the task, and set the parameters representing the spline. Then you can call the `df?construct1d` routine to construct the spline. The format of the spline is defined by parameter `s_format`. The method for spline construction is defined by parameter `method`. Upon successful construction, the spline coefficients are available in the user-provided memory location in the format you set through the Data Fitting editor. For the available storage formats, see table "[Hint Values for Spline Coefficients](#)".

df?interpolate1d/df?interpolateex1d

Runs data fitting computations.

Syntax

Fortran:

```
status = dfsinterpolate1d(task, type, method, nsite, site, sitehint, ndorder, dorder,
                          datahint, r, rhint, cell)
```

```
status = dfdinterpolate1d(task, type, method, nsite, site, sitehint, ndorder, dorder,
                          datahint, r, rhint, cell)
```

```
status = dfsinterpolateex1d(task, type, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

```
status = dfdinterpolateex1d(task, type, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

C:

```
status = dfsInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,
datahint, r, rhint, cell)
```

```
status = dfdInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,
datahint, r, rhint, cell)
```

```
status = dfsInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

```
status = dfdInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
type	Fortran: INTEGER C: MKL_INT	Type of spline-based computations. The parameter takes one or more values combined with an OR operation. For the list of possible values, see table " Computation Types Supported by the df?interpolate1d/ df?interpolate1d Routines ".
method	Fortran: INTEGER C: MKL_INT	Computation method. The supported value is DF_METHOD_PP.
nsite	Fortran: INTEGER C: MKL_INT	Number of interpolation sites.
site	Fortran: REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d	Array of interpolation sites of size nsite. The structure of the array is defined by the sitehint parameter: <ul style="list-style-type: none"> • If sites form a non-uniform partition, the array should contain nsite values. • If sites form a uniform partition, the array should contain two entries that represent the left and the right interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.

Name	Type	Description
	C: float* for dfsInterpolate1D/ dfsInterpolateEx1D double* for dfdInterpolate1D/ dfdInterpolateEx1D	
<i>sitehint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of <i>sitehint</i> , see table " Hint Values for Interpolation Sites ". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
<i>ndorder</i>	Fortran: INTEGER C: MKL_INT	Maximal derivative order increased by one to be computed at interpolation sites.
<i>dorder</i>	Fortran: INTEGER DIMENSION(*) C: MKL_INT*	Array of size <i>ndorder</i> that defines the order of the derivatives to be computed at the interpolation sites. If all the elements in <i>dorder</i> are zero, the library computes the spline values only. If you do not need interpolation computations, set <i>ndorder</i> to zero and pass a NULL pointer to <i>dorder</i> .
<i>datahint</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d C: float* for dfsInterpolate1D/ dfsInterpolateEx1D double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array that contains additional information about the structure of partition <i>x</i> and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the <i>datahint</i> array, see table " Structure of the datahint Array ".
<i>r</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfsinterpolate1d/ dfsinterpolateex1d REAL(KIND=8) DIMENSION(*) for dfdinterpolate1d/ dfdinterpolateex1d C: float* for dfsInterpolate1D/ dfsInterpolateEx1D	Array that contains results of computations at the interpolation sites. If you do not need spline-based interpolation or integration, set this pointer to NULL.

Name	Type	Description
	double* for dfdInterpolate1D/ dfdInterpolateEx1D	
<i>rhint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table " Hint Values for the <i>rhint</i> Parameter ". If you set the flag to DF_NO_HINT, the library stores the result in row-major format.
<i>cell</i>	Fortran: INTEGER DIMENSION(*) C: MKL_INT*	Array of cell indices in partition <i>x</i> that contain the interpolation sites. If you do not need cell indices, set this parameter to NULL.
<i>le_cb</i>	Fortran: INTEGER C: dfsInterpCallBack for dfdInterpolateEx1D dfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for extrapolation at the sites to the left of the interpolation interval.
<i>le_params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function.
<i>re_cb</i>	Fortran: INTEGER C: dfsInterpCallBack for dfdInterpolateEx1D dfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for extrapolation at the sites to the right of the interpolation interval.
<i>re_params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function.
<i>i_cb</i>	Fortran: INTEGER C: dfsInterpCallBack for dfdInterpolateEx1D dfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for interpolation within the interpolation interval.
<i>i_params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function.
<i>search_cb</i>	Fortran: INTEGER C: dfsSearchCellsCallBack for dfsInterpolateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites.

Name	Type	Description
	dfdSearchCellsCallBack for dfdInterpolateEx1D	
search_params	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function.

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none">• DF_STATUS_OK if the routine execution completed successfully.• Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?interpolate1d/df?interpolateex1d` routine performs spline-based computations with user-defined settings. The routine supports two types of computations for interpolation sites provided in array `site`:

Computation Types Supported by the `df?interpolate1d/df?interpolateex1d` Routines

Type	Description
DF_INTERP	Compute derivatives of predefined order. The derivative of the zero order is the spline value.
DF_CELL	Compute indices of cells in partition <code>x</code> that contain the sites.

If the sites do not belong to interpolation interval $[a, b]$, the library uses:

- polynomial P_0 of the spline constructed on interval $[x_0, x_1]$ for computations at the sites to the left of a .
- polynomial P_{n-2} of the spline constructed on interval $[x_{n-2}, x_{n-1}]$ for computations at the sites to the right of b .

Interpolation sites support the following hints:

Hint Values for Interpolation Sites

Value	Description
DF_NON_UNIFORM_PARTITION	Partition is non-uniform.
DF_UNIFORM_PARTITION	Partition is uniform.
DF_SORTED_DATA	Interpolation sites are sorted in the ascending order and define a non-uniform partition.
DF_NO_HINT	No hint is provided. By default, the partition defined by interpolation sites is interpreted as non-uniform.

NOTE If you pass a sorted array of interpolation sites to the Intel MKL, set the `sitehint` parameter to the `DF_SORTED_DATA` value. The library uses this information when choosing the search algorithm and ignores any other data hints about the structure of the interpolation sites.

Data Fitting computation routines can use the following hints to speed up the computation:

- `DF_UNIFORM_PARTITION` describes the structure of breakpoints and the interpolation sites.
- `DF_QUASI_UNIFORM_PARTITION` describes the structure of breakpoints.

Pass the above hints to the library when appropriate.

The `r` pointer defines the memory location for the sets of interpolation and integration results for all coordinates of function `y`. The sets are stored one by one, in the successive order of the function coordinates from y_1 to y_n .

You can define the following settings for packing the results within each set:

- Computation type: interpolation, integration, or both.
- Computation parameters: derivative orders.
- Storage format for the results. You can specify the format using the `rhint` parameter values described in the table below:

Hint Values for the `rhint` Parameter

Value	Description
<code>DF_MATRIX_STORAGE_ROWS</code>	Data is stored in row-major format according to C conventions.
<code>DF_MATRIX_STORAGE_COLS</code>	Data is stored in column-major format according to Fortran conventions.
<code>DF_NO_HINT</code>	No hint is provided. By default, the results are stored in row-major format.

For spline-based interpolation, you should set the derivatives whose values are required for the computation. You can provide the derivatives by setting the `dorder` array of size `ndorder` as follows:

$$dorder[i] = \begin{cases} 1, & \text{if derivative of the } i\text{-th order is required} \\ 0, & \text{otherwise} \end{cases} \quad i = 0, \dots, ndorder - 1$$

See below a common structure of the storage formats of the interpolation results within each set `r` for computing derivatives of order i_1, i_2, \dots, i_m at `nsite` interpolation sites. In this description, j is the coordinate of the vector-valued function:

- Row-major format

$r_j(i_1, 0)$	$r_j(i_2, 0)$...	$r_j(i_m, 0)$
$r_j(i_1, 1)$	$r_j(i_2, 1)$...	$r_j(i_m, 1)$
...
$r_j(i_1, nsite - 1)$	$r_j(i_2, nsite - 1)$...	$r_j(i_m, nsite - 1)$

- Column-major format

$r_j(i_1, 0)$	$r_j(i_1, 1)$...	$r_j(i_1, nsite - 1)$
$r_j(i_2, 0)$	$r_j(i_2, 1)$...	$r_j(i_2, nsite - 1)$
...

$r_j(i_m, 0)$	$r_j(i_m, 1)$...	$r_j(i_m, nsite - 1)$
---------------	---------------	-----	-----------------------

To speed up Data Fitting computations, use the `datahint` parameter that provides additional information about the structure of the partition and interpolation sites. This data represents a floating-point or a double array with the following structure:

Structure of the `datahint` Array

Element Number	Description
0	Task dimension
1	Type of additional information
2	Reserved field
3	The total number q of elements containing additional information.
4	Element (1)
...	...
$q+3$	Element (q)

Data Fitting computation functions support the following types of additional information for `datahint[1]`:

Types of Additional Information

Type	Element Number	Parameter
<code>DF_NO_APRIORI_INFO</code>	0	No parameters are provided. Information about the data structure is absent.
<code>DF_APRIORI_MOST_LIKELY_CELL</code>	1	Index of the cell that is likely to contain interpolation sites.

To compute indices of the cells that contain interpolation sites, provide the pointer to the array of size `nsite` for the results. The library supports the following scheme of cell indexing for the given partition $\{x_i\}$, $i=1,\dots,nx$:

$cell[j] = i$, if $site[j] \in [x_i, x_{i+1})$, $i = 0, \dots, nx$,

where

- $x_0 = -\infty$
- $x_{nx+1} = +\infty$
- $j = 0, \dots, nsite-1$

To perform interpolation computations with spline types unsupported in the Data Fitting component, use the extended version of the routine `df?interpolateex1d`. With this routine, you can provide user-defined callback functions for computations within, to the left of, or to the right of interpolation interval $[a, b]$. The callback functions compute indices of the cells that contain the specified interpolation sites or can serve as an approximation for computing the exact indices of such cells.

If you do not pass any function for computations at the sites outside the interval $[a, b]$, the routine uses the default settings.

See Also

[df?interpcallback](#)

[df?searchcellscallback](#)

df?integrate1d/df?integrateex1d

Computes a spline-based integral.

Syntax

Fortran:

```
status = dfsintegrate1d(task, method, nlim, llim, llimhint, rlim, rlimhint, ldatahint,
rdatahint, r, rhint)

status = dfdintegrate1d(task, method, nlim, llim, llimhint, rlim, rlimhint, ldatahint,
rdatahint, r, rhint)

search_cb, search_params)
```

Include Files

- Fortran: mkl_df.f90
- C: mkl.h

Input Parameters

Name	Type	Description
task	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task.
method	Fortran: INTEGER C: MKL_INT	Integration method. The supported value is DF_METHOD_PP.
nlim	Fortran: INTEGER C: MKL_INT	Number of pairs of integration limits.

Name	Type	Description
<i>llim</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d C: float* for dfsIntegrate1D/ dfsIntegrateEx1D double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array of size <i>nlim</i> that defines the left-side integration limits.
<i>llimhint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of the left-side integration limits <i>llim</i> . For the list of possible values of <i>llimhint</i> , see table " Hint Values for Integration Limits ". If you set the flag to the DF_NO_HINT value, the library assumes that the left-side integration limits define a non-uniform partition.
<i>rlim</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d C: float* for dfsIntegrate1D/ dfsIntegrateEx1D double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array of size <i>nlim</i> that defines the right-side integration limits.
<i>rlimhint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of the right-side integration limits <i>rlim</i> . For the list of possible values of <i>rlimhint</i> , see table " Hint Values for Integration Limits ". If you set the flag to the DF_NO_HINT value, the library assumes that the right-side integration limits define a non-uniform partition.
<i>ldatahint</i>	Fortran: REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d	Array that contains additional information about the structure of partition <i>x</i> and left-side integration limits. For details on the <i>ldatahint</i> array, see table " Structure of the datahint Array " in the description of the <i>df?Interpolate1D</i> function.

Name	Type	Description
	<pre>REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d</pre> <p>C: float* for dfsIntegrate1D/ dfsIntegrateEx1D</p> <pre>double* for dfdIntegrate1D/ dfdIntegrateEx1D</pre>	
<i>rdatahint</i>	<p>Fortran: REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d</p> <pre>REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d</pre> <p>C: float* for dfsIntegrate1D/ dfsIntegrateEx1D</p> <pre>double* for dfdIntegrate1D/ dfdIntegrateEx1D</pre>	Array that contains additional information about the structure of partition <i>x</i> and right-side integration limits. For details on the <i>rdatahint</i> array, see table " Structure of the <i>datahint</i> Array " in the description of the df?Interpolate1D function.
<i>r</i>	<p>Fortran: REAL(KIND=4) DIMENSION(*) for dfsintegrate1d/ dfsintegrateex1d</p> <pre>REAL(KIND=8) DIMENSION(*) for dfdintegrate1d/ dfdintegrateex1d</pre> <p>C: float* for dfsIntegrate1D/ dfsIntegrateEx1D</p> <pre>double* for dfdIntegrate1D/ dfdIntegrateEx1D</pre>	Array of integration results. The size of the array should be sufficient to hold <i>nlim</i> * <i>ny</i> values, where <i>ny</i> is the dimension of the vector-valued function. The integration results are packed according to the settings in <i>rhint</i> .
<i>rhint</i>	<p>Fortran: INTEGER</p> <p>C: MKL_INT</p>	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table " Hint Values for Integration Results ". If you set the flag to the DF_NO_HINT value, the library stores the results in row-major format.

Name	Type	Description
<i>le_cb</i>	Fortran: INTEGER C: dfsIntegrCallBack for dfsIntegrateEx1D dfdIntegrCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval [$llim[i]$, $\min(rlim[i], a)$) for $llim[i] < a$.
<i>le_params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function.
<i>re_cb</i>	Fortran: INTEGER C: dfsInterpCallBack for dfsIntegrateEx1D dfdInterpCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval [$\max(llim[i], b)$, $rlim[i]$] for $rlim[i] \geq b$.
<i>re_params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function.
<i>i_cb</i>	Fortran: INTEGER C: dfsIntegrCallBack for dfsIntegrateEx1D dfdIntegrCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval [$\max(a, llim[i],), \min(rlim[i], b)$).
<i>i_params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function.
<i>search_cb</i>	Fortran: INTEGER C: dfsSearchCellsCallBack for dfsIntegrateEx1D dfdSearchCellsCallBack for dfdIntegrateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites.
<i>search_params</i>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function.

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully.

Name	Type	Description
		<ul style="list-style-type: none"> Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?integrate1d/df?integrateex1d` routine computes spline-based integral on user-defined intervals

$$I(i, j) = \int_{rlim[i]}^{rlim[i+1]} f_j(x) dx, i = 0, \dots, nlim-1, j = 0, \dots, ny-1$$

If $rlim[i] < llim[i]$, the routine returns

$$I(i, j) = - \int_{rlim[i]}^{llim[i]} f_j(x) dx$$

The routine supports the following hint values for integration results:

Hint Values for Integration Results

Value	Description
<code>DF_MATRIX_STORAGE_ROWS</code>	Data is stored in row-major format according to C conventions.
<code>DF_MATRIX_STORAGE_COLS</code>	Data is stored in column-major format according to Fortran conventions.
<code>DF_NO_HINT</code>	No hint is provided. By default, the coordinates of vector-valued function y are provided and stored in row-major format.

A common structure of the storage formats for the integration results is as follows:

- Row-major format

$I(0, 0)$...	$I(0, nlim - 1)$
...
$I(ny - 1, 0)$...	$I(ny - 1, nlim - 1)$

- Column-major format

$I(0, 0)$...	$I(ny - 1, 0)$
...
$I(0, nlim - 1)$...	$I(ny - 1, nlim - 1)$

Using the `llimhint` and `rlimhint` parameters, you can provide the following hint values for integration limits:

Hint Values for Integration Limits

Value	Description
<code>DF_SORTED_DATA</code>	Integration limits are sorted in the ascending order and define a non-uniform partition.

Value	Description
DF_NON_UNIFORM_PARTITION	Partition defined by integration limits is non-uniform.
DF_UNIFORM_PARTITION	Partition defined by integration limits is uniform.
DF_NO_HINT	No hint is provided. By default, partition defined by integration limits is interpreted as non-uniform.

To compute integration with splines unsupported in the Data Fitting component, use the extended version of the routine `df?integrateex1d`. With this routine, you can provide user-defined callback functions that compute:

- integrals within, to the left of, or to the right of the interpolation interval $[a, b]$
- indices of cells that contain the provided integration limits or can serve as an approximation for computing the exact indices of such cells

If you do not pass callback functions, the routine uses the default settings.

df?searchcells1d/df?searchcellsex1d

Searches sub-intervals containing interpolation sites.

Syntax

Fortran:

```
status = dfssearchcells1d(task, method, nsite, site, sitehint, datahint, cell)
status = dfdsearchcells1d(task, method, nsite, site, sitehint, datahint, cell)
status = dfssearchcellsex1d(task, method, nsite, site, sitehint, datahint, cell,
                           search_cb, search_params)
status = dfdsearchcellsex1d(task, method, nsite, site, sitehint, datahint, cell,
                           search_cb, search_params)
```

C:

```
status = dfsSearchCells1D(task, method, nsite, site, sitehint, datahint, cell)
status = dfdSearchCells1D(task, method, nsite, site, sitehint, datahint, cell)
status = dfsSearchCellsEx1D(task, method, nsite, site, sitehint, datahint, cell,
                           search_cb, search_params)
status = dfdSearchCellsEx1D(task, method, nsite, site, sitehint, datahint, cell,
                           search_cb, search_params)
```

Include Files

- C: `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	Fortran: TYPE (DF_TASK) C: DFTaskPtr	Descriptor of the task.
<i>method</i>	Fortran: INTEGER C: MKL_INT	Search method. The supported value is DF_METHOD_STD.
<i>nsite</i>	Fortran: INTEGER C: MKL_INT*	Number of interpolation sites.
<i>site</i>	Fortran: REAL (KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL (KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d C: float* for dfsSearchCells1D/ dfsSearchCellsEx1D double* for dfdSearchCells1D/ dfdSearchCellsEx1D	Array of interpolation sites of size <i>nSite</i> . The structure of the array is defined by the <i>sitehint</i> parameter: <ul style="list-style-type: none"> • If the sites form a non-uniform partition, the array should contain <i>nSite</i> values. • If the sites form a uniform partition, the array should contain two entries that represent the left-most and the right-most interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
<i>sitehint</i>	Fortran: INTEGER C: MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of <i>sitehint</i> , see table " Hint Values for Interpolation Sites ". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
<i>datahint</i>	Fortran: REAL (KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL (KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d C: float* for dfsSearchCells1D/ dfsSearchCellsEx1D double* for dfdSearchCells1D/ dfdSearchCellsEx1D	Array that contains additional information about the structure of partition <i>x</i> and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the <i>datahint</i> array, see table " Structure of the datahint Array ".
<i>cell</i>	Fortran: INTEGER DIMENSION(*) C: MKL_INT*	Array of cell indices in partition <i>x</i> that contain the interpolation sites.

Name	Type	Description
<code>search_cb</code>	Fortran: INTEGER C: dfsSearchCellsCallBack for dfsSearchCellsEx1D dfdSearchCellsCallBack for dfdSearchCellsEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites.
<code>search_params</code>	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to additional user-defined parameters passed by the library to the <code>search_cb</code> function.

Output Parameters

Name	Type	Description
<code>status</code>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?searchcells1d/df?searchcellsex1d` routines return array `cell` of indices of sub-intervals (cells) in partition `x` that contain interpolation sites available in array `site`. For details on the cell indexing scheme, see the description of the `df?interpolate1d/df?interpolateex1d` computation routines.

Use the `datahint` parameter to provide additional information about the structure of the partition and/or interpolation sites. The definition of the `datahint` parameter is available in the description of the `df?interpolate1d/df?interpolateex1d` computation routines.

For description of the user-defined callback for computation of cell indices, see `df?searchcellscallback`.

<i>params</i>	Fortran: INTEGER DIMENSION (*)	Pointer to user-defined parameters of the callback function.
	C: void*	

Output Parameters

Name	Type	Description
<i>status</i>	Fortran: INTEGER	<p>The status returned by the callback function:</p> <ul style="list-style-type: none"> • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • A positive value indicates a warning. <p>See "Task Status and Error Reporting" for error code definitions.</p>

Description

When passed into the `df?integrateex1d` routine, this function defines integration computations. If at least one of the integration limits is outside the interpolation interval $[a, b]$, the library decomposes the integration into sub-intervals that belong to the extrapolation range to the left of a , the extrapolation range to the right of b , and the interpolation interval $[a, b]$, as follows:

- If the left integration limit is to the left of the interpolation interval ($llim < a$), the `df?integrateex1d` routine passes $llim$ as the left integration limit and $\min(rlim, a)$ as the right integration limit to the user-defined callback function.
- If the right integration limit is to the right of the interpolation interval ($rlim > b$), the `df?integrateex1d` routine passes $\max(llim, b)$ as the left integration limit and $rlim$ as the right integration limit to the user-defined callback function.
- If the left and the right integration limits belong to the interpolation interval, the `df?integrateex1d` routine passes them to the user-defined callback function unchanged.

The value of the integral is the sum of integral values obtained on the sub-intervals.

`df?integrate1d/df?integrateex1d`

`df?integrcallback`

`df?searchcellscallback`

`df?searchcellscallback`

A callback function for user-defined search to be passed into `df?interpolateex1d` or `df?searchcellsex1d`.

Syntax

Fortran:

```
status = dfssearchcellscallback(n, site, cell, flag, params)
status = dfdsearchcellscallback(n, site, cell, flag, params)
```

C:

```
status = dfsSearchCellsCallBack(n, site, cell, flag, params)
status = dfdSearchCellsCallBack(n, site, cell, flag, params)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>n</code>	Fortran: INTEGER(KIND=8) C: long long*	Number of interpolation sites.
<code>site</code>	Fortran: REAL(KIND=4) DIMENSION(*) for <code>dfssearchcellscallback</code>	Array of interpolation sites of size <code>n</code> .

Name	Type	Description
	REAL(KIND=8) DIMENSION(*) for dfdsearchcellscallback C: float* for dfsSearchCellsCallBack double* for dfdSearchCellsCallBack	
cell	Fortran: INTEGER(KIND=8) DIMENSION(*) C: long long*	Array of size n that returns indices of the cells computed by the callback function.
flag	Fortran: INTEGER(KIND=4) DIMENSION(*) C: int*	Array of size n , with values set as follows: <ul style="list-style-type: none"> If the cell with index $cell[i]$ contains $site[i]$, set $flag[i]$ to 1. Otherwise, set $flag[i]$ to zero. In this case, the library interprets the index as an approximation and computes the index of the cell containing $site[i]$ by using the provided index as a starting point for the search.
params	Fortran: INTEGER DIMENSION(*) C: void*	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
status	Fortran: INTEGER C: int	The status returned by the callback function: <ul style="list-style-type: none"> Zero indicates successful completion of the callback operation. A negative value indicates an error. The DF_STATUS_EXACT_RESULT status indicates that cell indices returned by the callback function are exact. In this case, you do not need to initialize entries of the $flag$ array. A positive value indicates a warning. See " Task Status and Error Reporting " for error code definitions.

Description

When passed into the `df?interpolateex1d` or `df?searchcellsex1d` routine, this function performs a user-defined search.

Task Destroyors

Task destructors are routines used to delete task descriptors and deallocate the corresponding memory resources. The Data Fitting task destructor `dfdeletetask` destroys a Data Fitting task and frees the memory.

`dfdeletetask`

Destroys a Data Fitting task object and frees the memory.

Syntax

Fortran:

```
status = dfdeletetask(task)
```

C:

```
status = dfDeleteTask(&task)
```

Include Files

- Fortran: `mkl_df.f90`
- C: `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	Fortran: TYPE(DF_TASK) C: DFTaskPtr	Descriptor of the task to destroy.

Output Parameters

Name	Type	Description
<code>status</code>	Fortran: INTEGER C: int	Status of the routine: <ul style="list-style-type: none"> <code>DF_STATUS_OK</code> if the task is deleted successfully. Non-zero error code if the operation failed. See "Task Status and Error Reporting" for error code definitions.

Description

Given a pointer to a task descriptor, this routine deletes the Data Fitting task descriptor and frees the memory allocated for the structure. If the task is deleted successfully, the routine sets the task pointer to `NULL`. Otherwise, the routine returns an error code.

A

Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $\mathbf{A}\mathbf{x} = \mathbf{b}$, where \mathbf{A} is an m -by- n matrix, \mathbf{x} is the n element column vector and \mathbf{b} is the m element column vector. The matrix \mathbf{A} is usually referred to as the coefficient matrix, and the vectors \mathbf{x} and \mathbf{b} are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in section [Sparse Linear Systems](#) that follows.

Sparse Linear Systems

In many real-life applications, most of the elements in \mathbf{A} are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $\mathbf{A}\mathbf{x} = \mathbf{b}$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix \mathbf{A} . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently for the right applications, iterative solvers can be very efficient.

Direct Solvers, on the other hand, often factor the matrix \mathbf{A} into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array \mathbf{A} .

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row i and column j in matrix \mathbf{A} is denoted by $a(i, j)$. For example, a 3 by 4 matrix \mathbf{A} , is written as follows:

$$\mathbf{A} = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix A with the property that $a(i,j) = a(j,i)$, is called a symmetric matrix. A complex matrix A with the property that $a(i,j) = \text{conj}(a(j,i))$, is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix A is the matrix obtained by “flipping” the elements of the array about its diagonal. That is, we exchange the elements $a(i,j)$ and $a(j,i)$. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix A are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix A is said to be positive definite if the vector-matrix product $x^T A x$ is greater than zero for all non-zero vectors x . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A , the result of the matrix product PA is identical to A except for interchanging the rows of A . For a square matrix, it can be shown that if PA is a permutation of the rows of A , then AP^T is the same permutation of the columns of A . Additionally, it can be shown that the inverse of P is P^T .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i -th row of a matrix to the j -th row, then the i -th element of the permutation vector is j .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U , such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUX &= b \\ \Rightarrow L(Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A , that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H . Consequently, a solver can increase its efficiency by only storing L , and one-half of A , and not computing U . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L , D , and half of A and we need not compute U . However, the backward solve phases must be amended to solving $L^T x = D^{-1} y$ rather than $L^T x = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is a symmetric positive definite sparse matrix, and A and b are defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & 1 & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & * & 5 & * \\ 3 & * & * & 8 & 16 \end{bmatrix}, \quad b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of A . The Cholesky factorization of A is: $A = LL^T$, where L is the following:

$$L = \begin{bmatrix} 3 & * & * & * & * \\ \frac{1}{2} & \frac{1}{2} & * & * & * \\ 2 & -2 & 2 & * & * \\ \frac{1}{4} & -4 & -2 & \frac{1}{2} & * \\ 1 & -1 & -2 & -3 & 1 \end{bmatrix}$$

Notice that even though the matrix A is relatively sparse, the lower triangular matrix L has no zeros below the diagonal. If we computed L and then used it for the forward and backward solve phase, we would do as much computation as if A had been dense.

The situation of L having non-zeros in places where A has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of A in such a way as to reduce the fill-in when computing L . By doing this, the solver would only need to compute the non-zero entries in L . Toward this end, consider permuting the rows and columns of A . As described in [Matrix Fundamentals](#) section, the permutations of the rows of A can be represented as a permutation matrix, P . The result of permuting the rows is the product of P and A . Suppose, in the above example, we swap the first and fifth row

of A , then swap the first and fifth columns of A , and call the resulting matrix B . Mathematically, we can express the process of permuting the rows and columns of A to get B as $B = PAP^T$. After permuting the rows and columns of A , we see that B is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & 2 & & & 2 \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since B is obtained from A by simply switching rows and columns, the numbers of non-zero entries in A and B are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with B is much smaller than the fill-in associated with A . Consequently, the storage and computation time needed to factor B is much smaller than to factor A . Based on this, we see that an efficient sparse solver needs to find permutation P of the matrix A , which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of B to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general LU decomposition. Specifically, let P be a permutation matrix, $B = PAP^T$ and suppose that B can be factored as $B = LU$. Then

$$Ax = b$$

$$\Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^TP)x = Pb$$

$$\Rightarrow (PAP^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an LU factorization for B , we can solve the original system of equations by a three step process:

1. Solve $Ly = Pb$.
2. Solve $Uz = y$.
3. Set $x = P^T z$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$Ly = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

$$\text{This gives: } Y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{3}}{12}.$$

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since a Cholesky factorization is used, $L^T z = y$.

$$\begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}^{-T} * \begin{bmatrix} z_1 \\ z_2 \\ z_3 \\ z_4 \\ z_5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{3}}{12} \end{bmatrix}$$

This gives $z^T = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}$.

The third and final step is to set $x = P^T z$. This gives $X^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}$.

Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

The storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

<i>values</i>	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column that contains the <i>i</i> -th element in the <i>values</i> array.
<i>rowIndex</i>	Element <i>j</i> of the integer array <i>rowIndex</i> gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the *i*-th row is equal to the difference of *rowIndex(i)* and *rowIndex(i+1)*.

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

NOTE The Intel MKL sparse storage scheme for the direct sparse solvers supports both with one-based indexing and zero-based indexing.

Consider the symmetric matrix *A*:

$$A = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{bmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix A are as follows:

Storage Arrays for a Symmetric Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(1	2	4	2	3	4	5	4	5)
<i>rowIndex</i>	=	(1	4	5	8	9	10)			

zero-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(0	1	3	1	2	3	4	3	4)
<i>rowIndex</i>	=	(0	3	4	7	8	9)			

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix B :

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

The matrix B has 13 non-zero elements, and all of them are stored as follows:

Storage Arrays for a Non-Symmetric Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>rowIndex</i>	=	(0	3	5	8	11	13)							

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if $a(j,i)$ is not zero if and only if $a(j, i)$ is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value

is equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the `values` array. For example, the above matrix B can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{bmatrix}$$

The matrix B can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Storage Arrays for a Symmetrically Structured Matrix

one-based indexing	
<code>values</code>	= (1 -1 -3 -2 5 0 4 6 4 -4 2 7 8 0 -5)
<code>columns</code>	= (1 2 4 1 2 5 3 4 5 1 3 4 2 3 5)
<code>rowIndex</code>	= (1 4 7 10 13 16)
zero-based indexing	
<code>values</code>	= (1 -1 -3 -2 5 0 4 6 4 -4 2 7 8 0 -5)
<code>columns</code>	= (0 1 3 0 1 4 2 3 4 0 2 3 1 2 4)
<code>rowIndex</code>	= (0 3 6 9 12 15)

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the `values` array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the `values` array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the `values` array.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

This section describes in detail the sparse matrix storage formats supported in the current version of the Intel MKL Sparse BLAS Level 2 and Level 3.

CSR Format

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the `values`, `columns`, `pointerB`, and `pointerE`. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix A .

<code>values</code>	A real or complex array that contains the non-zero elements of A . Values of the non-zero elements of A are mapped into the <code>values</code> array using the row-major storage mapping described above.
<code>columns</code>	Element i of the integer array <code>columns</code> is the number of the column in A that contains the i -th value in the <code>values</code> array.

<i>pointerB</i>	Element j of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row j of A . Note that this index is equal to $\text{pointerB}(j) - \text{pointerB}(1)+1$.
<i>pointerE</i>	An integer array that contains row indices, such that $\text{pointerE}(j) - \text{pointerB}(1)$ is the index of the element in the <i>values</i> array that is last non-zero element in a row j of A .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in A . The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in A .

NOTE Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix B

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

can be represented in the CSR format as:

Storage Arrays for a Matrix in CSR Format

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>pointerB</i>	=	(1	4	6	9	12)								
<i>pointerE</i>	=	(4	6	9	12	14)								

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>pointerB</i>	=	(0	3	5	8	11)								
<i>pointerE</i>	=	(3	5	8	11	13)								

This storage format is used in the NIST Sparse BLAS library [Rem05].

Note that the storage format accepted for the direct sparse solvers and described above (see [Storage Formats for the Direct Sparse Solvers](#)) is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix B can be represented in this format (referred to as the 3-array variation of the CSR format) as:

Storage Arrays for a Matrix in CSR Format (3-Array Variation)

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
<i>rowIndex</i>	=	(1	4	6	9	12	14)							

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
---------------	---	----	----	----	----	---	---	---	---	----	---	---	---	-----

<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
<i>rowIndex</i>	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row J goes just after the set of non-zero elements in the row $J-1$.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

Comparing the array *rowIndex* from the [Table "Storage Arrays for a Non-Symmetric Example Matrix"](#) with the arrays *pointerB* and *pointerE* from the [Table "Storage Arrays for an Example Matrix in CSR Format"](#) it is easy to see that

```
pointerB(i) = rowIndex(i) for i=1, ..5;
pointerE(i) = rowIndex(i+1) for i=1, ..5.
```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
Subroutine name_routine(.... , values, columns, pointerB, pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
call name_routine(.... , values, columns, rowIndex, rowindex(2), ...).
```

CSC Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the column-major storage mapping.
<i>rows</i>	Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB(j) - pointerB(1)+1</i> .
<i>pointerE</i>	An integer array that contains column indices, such that <i>pointerE(j) - pointerB(1)</i> is the index of the element in the <i>values</i> array that is last non-zero element in a column <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

NOTE Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

The above matrix *B* can be represented in the CSC format as:

Storage Arrays for a Matrix in CSC Format

one-based indexing

<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(1	2	4	1	2	5	3	4	1	3	4	2	5)
<i>pointerB</i>	=	(1	4	7	9	12)								
<i>pointerE</i>	=	(4	7	9	12	14)								
zero-based indexing														
<i>values</i>	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
<i>rows</i>	=	(0	1	3	0	1	4	2	3	0	2	3	1	4)
<i>pointerB</i>	=	(0	3	6	8	11)								
<i>pointerE</i>	=	(3	6	8	11	13)								

Coordinate Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> in any order.
<i>rows</i>	Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.

NOTE Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{bmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{bmatrix}$$

can be represented in the coordinate format as follows:

Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>rows</i>	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
<i>columns</i>	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
<i>rows</i>	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)

<i>columns</i>	=	(0 1 2 0 1 2 3 4 0 2 3 1 4)
----------------	---	-----------------------------

Diagonal Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

<i>values</i>	A real or complex two-dimensional array is dimensioned as <i>lval</i> by <i>ndiag</i> . Each column of it contains the non-zero elements of certain diagonal of <i>A</i> . The key point of the storage is that each element in <i>values</i> retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of <i>distance</i> (<i>i</i>) is the number of elements to be padded for diagonal <i>i</i> .
<i>distance</i>	An integer array with dimension <i>ndiag</i> . Element <i>i</i> of the array <i>distance</i> is the distance between <i>i</i> -diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *c* can be represented in the diagonal storage format as follows:

$$\text{distance} = (-3 \ -1 \ 0 \ 1 \ 2)$$

$$\text{values} = \begin{bmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{bmatrix}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Skyline Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

<i>values</i>	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
<i>pointers</i>	An integer array with dimension $(m+1)$, where m is the number of rows for lower triangle (columns for the upper triangle). $\text{pointers}(i) - \text{pointers}(1)+1$ gives the index of element in <i>values</i> that is first non-zero element in row (column) i . The value of $\text{pointers}(m+1)$ is set to $nnz + \text{pointers}(1)$, where nnz is the number of elements in the array <i>values</i> .

For example, the low triangle of the matrix C given above can be stored as follows:

```
values = ( 1 -2 5 4 -4 0 2 7 8 0 0 -5 )
pointers = ( 1 2 4 5 9 13 )
```

and the upper triangle of this matrix C can be stored as follows:

```
values = ( 1 -1 5 -3 0 4 6 7 4 0 -5 )
pointers = ( 1 2 4 7 9 12 )
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format does not support general matrices.

BSR Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
<i>columns</i>	Element i of the integer array <i>columns</i> is the number of the column in the block matrix that contains the i -th non-zero block.
<i>pointerB</i>	Element j of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row j of the block matrix.
<i>pointerE</i>	Element j of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row j of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix D

$$D = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 1 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix D can be represented as a 3×3 block matrix E with the following structure:

$$E = \begin{bmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 1 \end{bmatrix}, P = \begin{bmatrix} 4 & 3 \\ 0 & 0 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The matrix D can be represented in the BSR format as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)
columns = (1 2 2 2 3)
pointerB = (1 3 4)
pointerE = (3 4 6)
```

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
columns = (0 1 1 1 2)
pointerB = (0 2 3)
pointerE = (2 3 5)
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Intel MKL supports the variation of the BSR format that is specified by three arrays: `values`, `columns`, and `rowIndex`. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
<i>columns</i>	Element i of the integer array <i>columns</i> is the number of the column in the block matrix that contains the i -th non-zero block.
<i>rowIndex</i>	Element j of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row j of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the i -th row is equal to the difference of $\text{rowIndex}(i)$ and $\text{rowIndex}(i+1)$.

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zeros blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix D can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0)
columns = (1 2 2 2 3)
rowIndex = (1 3 4 6)
```

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)
columns = (0 1 1 1 2)
rowIndex = (0 2 3 5)
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix F :

$$F = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix F can be represented as a 3×3 block matrix G with the following structure:

$$G = \begin{bmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, M' = \begin{bmatrix} 6 & 8 \\ 7 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 2 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The symmetric matrix F can be represented in this 3-array variation of the BSR format (storing only upper triangular) as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0)
```

```
columns = (1 2 2 3)
```

```
rowIndex = (1 3 4 5)
```

zero-based indexing

```
values = (1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0)
```

```
columns = (0 1 1 2)
```

```
rowIndex = (0 2 3 4)
```

Routine and Function Arguments

The major arguments in the BLAS routines are vector and matrix, whereas VML functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length n and increment $incx$ is passed in a one-dimensional array x whose values are defined as $x(1), x(1+|incx|), \dots, x(1+(n-1)*|incx|)$

If $incx$ is positive, then the elements in array x are stored in increasing order. If $incx$ is negative, the elements in array x are stored in decreasing order with the first element defined as $x(1+(n-1)*|incx|)$. If $incx$ is zero, then all elements of the vector have the same value, $x(1)$. The dimension of the one-dimensional array that stores the vector must always be at least

```
idimx = 1 + (n-1)*|incx|
```

Example. One-dimensional Real Array

Let $x(1:7)$ be the one-dimensional real array

```
x = (1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0).
```

If $incx = 2$ and $n = 3$, then the vector argument with elements in order from first to last is $(1.0, 5.0, 9.0)$.

If $incx = -2$ and $n = 4$, then the vector elements in order from first to last is $(13.0, 9.0, 5.0, 1.0)$.

If $incx = 0$ and $n = 4$, then the vector elements in order from first to last is $(1.0, 1.0, 1.0, 1.0)$.

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified. In Fortran, storing the m -by- n matrix is based on column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is m , and the increment between elements on the same diagonal is $m + 1$.

Example. Two-dimensional Real Matrix

Let a be the real 5×4 matrix declared as `REAL A (5,4)`.

To scale the third column of a by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
callsscal (5, 2.0, a(1,3), 1)
```

To scale the second row, use the statement:

```
callsscal (4, 2.0, a(2,1), 5)
```

To scale the main diagonal of A by 2.0, use the statement:

```
callsscal (5, 2.0, a(1,1), 6)
```

NOTE The default vector argument is assumed to be 1.

Vector Arguments in VML

Vector arguments of VML mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length n is passed contiguously in an array a whose values are defined as $a[0], a[1], \dots, a[n-1]$ (for the C interface).

To accommodate for arrays with other increments, or more complicated indexing, VML contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array a as

```
a[m0], a[m1], ..., a[mn-1]
```

and need to be regrouped into an array y as

```
y[k0], y[k1], ..., y[kn-1],
```

VML pack/unpack functions can use one of the following indexing methods:

Positive Increment Indexing

```
kj = incy * j, mj = inca * j, j = 0 ,..., n-1
```

Constraint: $\text{incy} > 0$ and $\text{inca} > 0$.

For example, setting $\text{incy} = 1$ specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

```
kj = iy[j], mj = ia[j], j = 0 ,..., n-1,
```

where ia and iy are arrays of length n that contain index vectors for the input and output arrays a and y , respectively.

Mask Vector Indexing

Indices kj , mj are such that:

```
my[kj] ≠ 0, ma[mj] ≠ 0 , j = 0,..., n-1,
```

where ma and my are arrays that contain mask vectors for the input and output arrays a and y , respectively.

Matrix Arguments

Matrix arguments of the Intel® Math Kernel Library routines can be stored in either one- or two-dimensional arrays, using the following storage schemes:

- **conventional full storage** (in a two-dimensional array)
- **packed storage** for Hermitian, symmetric, or triangular matrices (in a one-dimensional array)
- **band storage** for band matrices (in a two-dimensional array)
- **rectangular full packed storage** for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

Full storage is the following obvious scheme: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.

If a matrix is triangular (upper or lower, as specified by the argument *uplo*), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if *uplo* = 'U', a_{ij} is stored in $a(i,j)$ for $i \leq j$, other elements of a need not be set.
 if *uplo* = 'L', a_{ij} is stored in $a(i,j)$ for $j \leq i$, other elements of a need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument *uplo*) is packed by columns in a one-dimensional array *ap*:

if *uplo* = 'U', a_{ij} is stored in $ap(i+j(j-1)/2)$ for $i \leq j$

if *uplo* = 'L', a_{ij} is stored in $ap(i+(2*n-j)*(j-1)/2)$ for $j \leq i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in *p*.

Band storage is as follows: an m -by- n band matrix with k_1 non-zero sub-diagonals and k_u non-zero super-diagonals is stored compactly in a two-dimensional array *ab* with k_1+k_u+1 rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in rows of the array. Thus,

a_{ij} is stored in $ab(ku+1+i-j, j)$ for $\max(1, j-k_u) \leq i \leq \min(n, j+k_1)$.

Use the band storage scheme only when k_1 and k_u are much less than the matrix size n . Although the routines work correctly for all values of k_1 and k_u , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$m = n = 6$, $k_1 = 2$, $k_u = 1$

Array elements marked * are not used by the routines:

Banded matrix A

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$$

Band storage of A

$$\begin{array}{cccccc} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{array}$$

When a general band matrix is supplied for *LU factorization*, space must be allowed to store k_1 additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with $k_1 + k_u$ super-diagonals. Thus,

a_{ij} is stored in $ab(k_1+k_u+1+i-j, j)$ for $\max(1, j-k_u) \leq i \leq \min(n, j+k_1)$.

The band storage scheme for LU factorization is illustrated by the following example, when $m = n = 6$, $k_1 = 2$, $k_u = 1$:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0	*	*	*	+	+	+
a_{21}	a_{22}	a_{23}	0	0	0	*	*	+	+	+	+
a_{31}	a_{32}	a_{33}	a_{34}	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	0	a_{64}	a_{65}	a_{66}	a_{31}	a_{42}	a_{53}	a_{64}	*	*

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

*	*	*	U_{14}	U_{25}	U_{36}
*	*	U_{13}	U_{24}	U_{35}	U_{46}
*	U_{12}	U_{23}	U_{34}	U_{45}	U_{56}
U_{11}	U_{22}	U_{33}	U_{44}	U_{55}	U_{66}
m_{21}	m_{32}	m_{43}	m_{54}	m_{65}	*
m_{31}	m_{42}	m_{53}	m_{64}	*	*

where u_{ij} are the elements of the upper triangular matrix U , and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either $k_1 = 0$ if upper triangular, or $k_u = 0$ if lower triangular. For symmetric or Hermitian band matrices with k sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument `uplo`:

if $uplo = 'U'$, a_{ij} is stored in $ab(k+1+i-j, j)$ for $\max(1, j-k) \leq i \leq j$

if $uplo = 'L'$, a_{ij} is stored in $ab(1+i-j, j)$ for $j \leq i \leq \min(n, j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n'	normal (no conjugation, no transposition)
'T' or 't'	transpose
'C' or 'c'	conjugate transpose.

Example. Two-Dimensional Complex Array

Suppose `A (1:5, 1:4)` is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let `transa` be the transposition parameter, `m` be the number of rows, `n` be the number of columns, and `lda` be the leading dimension. Then if

`transa = 'N'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'T'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (2.1, 0.21) & (3.1, 0.31) & (4.1, 0.41) \\ (1.2, 0.12) & (2.2, 0.22) & (3.2, 0.32) & (4.2, 0.42) \end{bmatrix}$$

If `transa = 'C'`, `m = 4`, `n = 2`, and `lda = 5`, the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array `A` above is declared as `COMPLEX A (5,4)`.

Then if `transa = 'N'`, `m = 3`, `n = 4`, and `lda = 4`, the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

Rectangular Full Packed storage allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an n -by- n triangle (and suppose for simplicity that n is even), you partition the triangle into three parts: two $n/2$ -by- $n/2$ triangles and an $n/2$ -by- $n/2$ square, then pack this as an n -by- $n/2$ rectangle (or $n/2$ -by- n rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when n is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

n is odd, A is lower triangular

Full format	RFP (not transposed)	RFP (transposed)
$a_{11} \quad x \quad x \quad x \quad x \quad x \quad x$	$a_{11} \quad a_{55} \quad a_{65} \quad a_{75}$	$a_{11} \quad a_{21} \quad a_{31} \quad a_{41} \quad \mathbf{a_{51}} \quad \mathbf{a_{61}} \quad \mathbf{a_{71}}$
$a_{21} \quad a_{22} \quad x \quad x \quad x \quad x \quad x$	$a_{21} \quad a_{22} \quad a_{66} \quad a_{76}$	$a_{55} \quad a_{22} \quad a_{32} \quad a_{42} \quad \mathbf{a_{52}} \quad \mathbf{a_{62}} \quad \mathbf{a_{72}}$
$a_{31} \quad a_{32} \quad a_{33} \quad x \quad x \quad x \quad x$	$a_{31} \quad a_{32} \quad a_{33} \quad a_{77}$	$a_{65} \quad a_{66} \quad a_{33} \quad a_{43} \quad \mathbf{a_{53}} \quad \mathbf{a_{63}} \quad \mathbf{a_{73}}$
$a_{41} \quad a_{42} \quad a_{43} \quad a_{44} \quad x \quad x \quad x$	$a_{41} \quad a_{42} \quad a_{43} \quad a_{44}$	$a_{75} \quad a_{76} \quad a_{77} \quad a_{44} \quad \mathbf{a_{54}} \quad \mathbf{a_{64}} \quad \mathbf{a_{74}}$

Intel MKL provides a number of routines such as [?hfrk](#), [?sfrk](#) performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, [?pttf](#) goes from the standard packed format to RFP and [?trttf](#) goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

Code Examples

This appendix presents code examples of using some Intel MKL routines and functions. You can find here example code written in both Fortran and C.

Please refer to respective chapters in the manual for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors `x` and `y`.

Parameters

<code>n</code>	Specifies the number of elements in vectors <code>x</code> and <code>y</code> .
<code>incx</code>	Specifies the increment for the elements of <code>x</code> .
<code>incy</code>	Specifies the increment for the elements of <code>y</code> .

```
program dot_main
real x(10), y(10), sdot, res
integer n, incx, incy, i
external sdot
n = 5
incx = 2
incy = 1
do i = 1, 10
    x(i) = 2.0e0
    y(i) = 1.0e0
end do
res = sdot (n, x, incx, y, incy)
print*, `SDOT = ', res
end
```

As a result of this program execution, the following line is printed:

`SDOT = 10.000`

Example. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector `x` to a vector `y`.

Parameters

<code>n</code>	Specifies the number of elements in vectors <code>x</code> and <code>y</code> .
<code>incx</code>	Specifies the increment for the elements of <code>x</code> .
<code>incy</code>	Specifies the increment for the elements of <code>y</code> .

```
program copy_main
real x(10), y(10)
integer n, incx, incy, i
n = 3
```

```

incx = 3
incy = 1
do i = 1, 10
  x(i) = i
end do
call scopy (n, x, incx, y, incy)
print*, `Y = ', (y(i), i = 1, n)
end

```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

```
c := alpha*x*y' + a.
```

Parameters

<code>alpha</code>	Specifies a scalar <code>alpha</code> .
<code>x</code>	m -element vector.
<code>y</code>	n -element vector.
<code>a</code>	m -by- n matrix.

```

program ger_main
real a(5,3), x(10), y(10), alpha
integer m, n, incx, incy, i, j, lda
m = 2
n = 3
lda = 5
incx = 2
incy = 1
alpha = 0.5
do i = 1, 10
  x(i) = 1.0
  y(i) = 1.0
end do
do i = 1, m
  do j = 1, n
    a(i,j) = j
  end do
end do
call sger (m, n, alpha, x, incx, y, incy, a, lda)
print*, `Matrix A:'
do i = 1, m
  print*, (a(i,j), j = 1, n)
end do
end

```

As a result of this program execution, matrix `a` is printed as follows:

Matrix A:

```

1.50000 2.50000 3.50000
1.50000 2.50000 3.50000

```

Example. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

```
c := alpha*a*b' + beta*c.
```

Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>beta</i>	Specifies a scalar <i>beta</i> .
<i>a</i>	Symmetric matrix
<i>b</i>	<i>m</i> -by- <i>n</i> matrix
<i>c</i>	<i>m</i> -by- <i>n</i> matrix

```
program symm main
real a(3,3), b(3,2), c(3,3), alpha, beta
integer m, n, lda, ldb, ldc, i, j
character uplo, side
uplo = 'u'
side = 'l'
m = 3
n = 2
lda = 3
ldb = 3
ldc = 3
alpha = 0.5
beta = 2.0
do i = 1, m
  do j = 1, m
    a(i,j) = 1.0
  end do
end do
do i = 1, m
  do j = 1, n
    c(i,j) = 1.0
    b(i,j) = 2.0
  end do
end do
call ssymm (side, uplo, m, n, alpha,
a, lda, b, ldb, beta, c, ldc)
print*, `Matrix C: `
do i = 1, m
  print*, (c(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

```
5.00000 5.00000
5.00000 5.00000
5.00000 5.00000
```

The following example illustrates a call from a C program to the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Example. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure *c*.

```
#include <cstdio>
#include "mkl_blas.h"
#define N 5
void main()
{
  int n, inca = 1, incb = 1, i;
  MKL_Complex16 a[N], b[N], c;
  void zdotc();
  n = N;
  for( i = 0; i < n; i++ ){
    a[i].real = (double)i; a[i].imag = (double)i * 2.0;
    b[i].real = (double)(n - i); b[i].imag = (double)i * 2.0;
  }
```

```

zdotc( &c, &n, a, &inca, b, &incb );
printf( "The complex dot product is: ( %6.2f, %6.2f )\n", c.real, c.imag );
}

```

NOTE Instead of calling BLAS directly from C programs, you might wish to use the C interface to the Basic Linear Algebra Subprograms (CBLAS) implemented in Intel® MKL. See [C Interface Conventions](#) for more information.

Fourier Transform Functions Code Examples

This section presents code examples of functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” sections in the “Fourier Transform Functions” chapter. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- Auxiliary data transformations.

FFT Code Examples

This section presents code examples of using the FFT interface functions described in “[Fourier Transform Functions](#)” chapter. Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

One-dimensional In-place FFT (Fortran Interface)

```

! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X(32)
Real :: Y(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
!...put input data into X(1),...,X(32); Y(1),...,Y(32)

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE, &
    DFTI_COMPLEX, 1, 32 )
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X )
Status = DftiFreeDescriptor( My_Desc1_Handle )
! result is given by {X(1),X(2),...,X(32)}

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE, &
    DFTI_REAL, 1, 32 )
Status = DftiCommitDescriptor( My_Desc2_Handle )
Status = DftiComputeForward( My_Desc2_Handle, Y )
Status = DftiFreeDescriptor( My_Desc2_Handle )
! result is given in CCS format.

```

One-dimensional Out-of-place FFT (Fortran Interface)

```

! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_in(32)
Complex :: X_out(32)
Real :: Y_in(32)
Real :: Y_out(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status

```

```

...put input data into X_in(1),...,X_in(32); Y_in(1),...,Y_in(32)
! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,
DFTI_COMPLEX, 1, 32 )
Status = DftiSetValue( My_Desc1_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X_in, X_out )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X_out(1),X_out(2),...,X_out(32)}
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,
DFTI_REAL, 1, 32)
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y_in, Y_out)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by Y_out in CCS format.

```

One-dimensional In-place FFT (C Interface)

```

/* C example, float_Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x[32];
float y[34];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x[0],...,x[31]; y[0],...,y[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x );
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x[0], ..., x[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 1, 32);
status = DftiCommitDescriptor( my_desc2_handle );
status = DftiComputeForward( my_desc2_handle, y );
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given in CCS format*/

```

One-dimensional Out-of-place FFT (C Interface)

```

/* C example, float_Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x_in[32];
float _Complex x_out[32];
float y_in[32];
float y_out[34];

DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x_in[0],...,x_in[31]; y_in[0],...,y_in[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x_in, x_out );
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x_out[0], ..., x_out[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 1, 32);
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( My_Desc2_Handle);
status = DftiComputeForward( My_Desc2_Handle, y_in, y_out);

```

```
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*/
```

Two-dimensional FFT (Fortran Interface)

The following is an example of two simple two-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran example.
! 2D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_2D(32,100)
Real :: Y_2D(34, 102)
Complex :: X(3200)
Real :: Y(3468)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status, L(2)
!...put input data into X_2D(j,k), Y_2D(j,k), 1<=j<=32,1<=k<=100
!...set L(1) = 32, L(2) = 100
!...the transform is a 32-by-100

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE, &
    DFTI_COMPLEX, 2, L)
Status = DftiCommitDescriptor( My_Desc1_Handle)
Status = DftiComputeForward( My_Desc1_Handle, X)
Status = DftiFreeDescriptor( My_Desc1_Handle)
! result is given by X_2D(j,k), 1<=j<=32, 1<=k<=100

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE, &
    DFTI_REAL, 2, L)
Status = DftiCommitDescriptor( My_Desc2_Handle)
Status = DftiComputeForward( My_Desc2_Handle, Y)
Status = DftiFreeDescriptor( My_Desc2_Handle)
! result is given by the complex value z(j,k) 1<=j<=32; 1<=k<=100
! and is stored in CCS format
```

Two-dimensional FFT (C Interface)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x[32][100];
float y[34][102];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status, l[2];
//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 2, 1);
status = DftiCommitDescriptor( my_desc1_handle);
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor( &my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 2, 1);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor( &my_desc2_handle);
```

```
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/
```

The following examples demonstrate how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of the `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

Changing Default Settings (Fortran)

The code below illustrates how this can be done:

```
! Fortran example
! 1D complex to complex, not in place
Use MKL_DFTI
Complex :: X_in(32), X_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status
!...put input data into X_in(j), 1<=j<=32
Status = DftiCreateDescriptor( My_Desc_Handle, & DFTI_SINGLE, DFTI_COMPLEX, 1, 32)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X_in, X_out)
Status = DftiFreeDescriptor( My_Desc_Handle)
! result is X_out(1),X_out(2),...,X_out(32)
```

Changing Default Settings (C)

```
/* C99 example */
#include "mkl_dfti.h"
float Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status;
//...put input data into x_in[j], 0 <= j < 32
status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc_handle);
status = DftiComputeForward( my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is x_out[0], x_out[1], ..., x_out[31] */
```

Using Status Checking Functions

The example illustrates the use of status checking functions described in [Chapter 11](#).

```
/* C */
DFTI_DESCRIPTOR_HANDLE desc;
MKL_LONG status;
// ... descriptor creation and other code
status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status,DFTI_NO_ERROR))
{
    printf ('Error: %s\n', DftiErrorMessage(status));
}

! Fortran
type(DFTI_DESCRIPTOR), POINTER :: desc
integer status
! ...descriptor creation and other code
status = DftiCommitDescriptor(desc)
if (status .ne. 0) then
```

```

if (.not. DftiErrorClass(status,DFTI_NO_ERROR) then
    print *, 'Error: ', DftiErrorMessage(status)
endif
endif

```

Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```

! Fortran
use mkl_dfti
Complex :: X_2D(20,40)
Complex :: X(800)
Equivalence (X_2D, X)
INTEGER :: STRIDE(2)
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim1
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim2
!
Status = DftiCreateDescriptor(Desc_Handle_Dim1, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 20 )
Status = DftiCreateDescriptor(Desc_Handle_Dim2, DFTI_SINGLE,&
                             DFTI_COMPLEX, 1, 40 )
! perform 40 one-dimensional transforms along 1st dimension
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_INPUT_DISTANCE, 20 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_OUTPUT_DISTANCE, 20 )
Status = DftiCommitDescriptor( Desc_Handle_Dim1 )
Status = DftiComputeForward( Desc_Handle_Dim1, X )
! perform 20 one-dimensional transforms along 2nd dimension
Stride(1) = 0; Stride(2) = 20
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_STRIDES, Stride )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_STRIDES, Stride )
Status = DftiCommitDescriptor( Desc_Handle_Dim2 )
Status = DftiComputeForward( Desc_Handle_Dim2, X )
Status = DftiFreeDescriptor( Desc_Handle_Dim1 )
Status = DftiFreeDescriptor( Desc_Handle_Dim2 )

/* C */
#include "mkl_dfti.h"

status = DftiFreeDescriptor( &desc_handle_dim2 );
```

The following are examples of real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example "Two-Dimensional REAL In-place FFT \(Fortran Interface\)"](#) is two-dimensional in-place transform and [Example "Two-Dimensional REAL Out-of-place FFT \(Fortran Interface\)"](#) is two-dimensional out-of-place transform in Fortran interface. [Example "Three-Dimensional REAL FFT \(C Interface\)"](#) is three-dimensional out-of-place transform in C interface. Note that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

Two-Dimensional REAL In-place FFT (Fortran Interface)

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(34,100) ! 34 = (32/2 + 1)*2
Real :: X(3400)
Equivalence (X_2D, X)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_in(3)
Integer :: strides_out(3)
! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_in(1) = 0, strides_in(2) = 1, strides_in(3) = 34
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17
! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE,&
DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue(My_Desc_Handle, DFTI_INPUT_STRIDES, strides_in)
Status = DftiSetValue(My_Desc_Handle, DFTI_OUTPUT_STRIDES, strides_out)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X )
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in real matrix X_2D in CCE format.
```

Two-Dimensional REAL Out-of-place FFT (Fortran Interface)

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(32,100)
Complex :: Y_2D(17, 100) ! 17 = 32/2 + 1
Real :: X(3200)
Complex :: Y(1700)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_out(3)
! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
```

```

! ...set L(1) = 32, L(2) = 100
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17

! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle, &
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiSetValue( My_Desc_Handle, &
DFTI_OUTPUT_STRIDES, strides_out)

Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X, Y)
Status = DftiFreeDescriptor( My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in complex matrix Y_2D in CCE format.

```

Three-Dimensional REAL FFT (C Interface)

```

/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float _Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status, l[3];
MKL_LONG strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, l );
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE );
status = DftiSetValue( my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor( my_desc_handle);
status = DftiComputeForward( my_desc_handle, x, y);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value z(j,k,s) 0<=j<=31; 0<=k<=99, 0<=s<=9
and is stored in complex matrix y in CCE format. */

```

Examples of Using Multi-Threading for FFT Computation

The following sample program shows how to employ internal threading in Intel MKL for FFT computation (see case "a" in ["Number of user threads"](#)).

To specify the number of threads inside Intel MKL, use the following settings:

`set MKL_NUM_THREADS = 1` for one-threaded mode;

`set MKL_NUM_THREADS = 4` for multi-threaded mode.

Note that the configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must be equal to its default value 1.

Using Intel MKL Internal Threading Mode

```
#include "mkl_dfti.h"
```

```

int main ()
{
    float x[200][100];
    DFTI_DESCRIPTOR_HANDLE fft;
    MKL_LONG len[2] = {200, 100};
    // initialize x
    DftiCreateDescriptor ( &fft, DFTI_SINGLE, DFTI_REAL, 2, len );
    DftiCommitDescriptor ( fft );
    DftiComputeForward ( fft, x );
    DftiFreeDescriptor ( &fft );
    return 0;
}

```

The following [Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region"](#) and [Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread"](#) illustrate a parallel customer program with each descriptor instance used only in a single thread (see cases "b" and "c" in [Number of user threads](#)).

Specify the number of threads for [Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region"](#) like this:

`set MKL_NUM_THREADS = 1` for Intel MKL to work in the single-threaded mode (recommended);

`set OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have its default value of 1.

Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL (case "a"). To achieve this, you need to set the parameter `DFTI_NUMBER_OF_TRANSFORMS = 4` and to set the corresponding parameter `DFTI_INPUT_DISTANCE = 5000`.

C code for the example is as follows:

```

#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    int th;
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(len, x)
    for (th = 0; th < nth; th++)
    {
        DFTI_DESCRIPTOR_HANDLE myFFT;

        DftiCreateDescriptor (&myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
        DftiCommitDescriptor (myFFT);
        DftiComputeForward (myFFT, x[th]);
        DftiFreeDescriptor (myFFT);
    }
    return 0;
}

```

Fortran code for the example is as follows:

```

program fft2d_private_descr_main
    use mkl_dfti

    integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
    parameter (nth = 4, len = (/50, 100/))
    complex x(len(2)*len(1), nth)

```

```

type(dfti_descriptor), pointer :: myFFT
integer th, myStatus

! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x) PRIVATE(myFFT, myStatus)
do th = 1, nth
    myStatus = DftiCreateDescriptor (myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
    myStatus = DftiCommitDescriptor (myFFT)
    myStatus = DftiComputeForward (myFFT, x(:, th))
    myStatus = DftiFreeDescriptor (myFFT)
end do
!$OMP END PARALLEL DO
end

```

Specify the number of threads for Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread" like this:

set MKL_NUM_THREADS = 1 for Intel MKL to work in the single-threaded mode (obligatory);

set OMP_NUM_THREADS = 4 for the customer program to work in the multi-threaded mode.

The configuration parameter DFTI_NUMBER_OF_USER_THREADS must have the default value of 1.

Using Parallel Mode with Multiple Descriptors Initialized in One Thread

C code for the example is as follows:

```

#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT[ARRAY_LEN(x)];
    int th;

    for (th = 0; th < nth; th++)
        DftiCreateDescriptor (&FFT[th], DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    for (th = 0; th < nth; th++)
        DftiCommitDescriptor (FFT[th]);
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
    for (th = 0; th < nth; th++)
        DftiComputeForward (FFT[th], x[th]);
    for (th = 0; th < nth; th++)
        DftiFreeDescriptor (&FFT[th]);
    return 0;
}

```

Fortran code for the example is as follows:

```

program fft2d_array_descr_main
    use mkl_dfti

    integer nth, len(2)
    ! 4 OMP threads, each does 2D FFT 50x100 points
    parameter (nth = 4, len = (/50, 100/))
    complex x(len(2)*len(1), nth)

    type thread_data
        type(dfti_descriptor), pointer :: FFT
    end type thread_data
    type(thread_data) :: workload(nth)

    integer th, status, myStatus

    do th = 1, nth
        status = DftiCreateDescriptor (workload(th)%FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
        status = DftiCommitDescriptor (workload(th)%FFT)
    end do

```

```

    end do
! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x, workload) PRIVATE(myStatus)
    do th = 1, nth
        myStatus = DftiComputeForward (workload(th)%FFT, x(:, th))
    end do
!$OMP END PARALLEL DO
    do th = 1, nth
        status = DftiFreeDescriptor (workload(th)%FFT)
    end do
end

```

The following [Example "Using Parallel Mode with a Common Descriptor"](#) illustrates a parallel customer program with a common descriptor used in several threads (see case "d" in ["Number of user threads"](#)).

In this case, the number of threads, as well as any other configuration parameter, must not be changed after FFT initialization by the `DftiCommitDescriptor()` function is done.

Using Parallel Mode with a Common Descriptor

C code for the example is as follows:

```

#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT;
    int th;

    DftiCreateDescriptor (&FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    DftiSetValue (FFT, DFTI_NUMBER_OF_USER_THREADS, nth);
    DftiCommitDescriptor (FFT);
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
    for (th = 0; th < nth; th++)
        DftiComputeForward (FFT, x[th]);
    DftiFreeDescriptor (&FFT);
    return 0;
}

```

Fortran code for the example is as follows:

```

program fft2d_shared_descr_main
use mkl_dfti

integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
parameter (nth = 4, len = (/50, 100/))
complex x(len(2)*len(1), nth)
type(dfti_descriptor), pointer :: FFT

integer th, status, myStatus

status = DftiCreateDescriptor (FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
status = DftiSetValue (FFT, DFTI_NUMBER_OF_USER_THREADS, nth)
status = DftiCommitDescriptor (FFT)
! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x, FFT) PRIVATE(myStatus)
    do th = 1, nth
        myStatus = DftiComputeForward (FFT, x(:, th))
    end do
!$OMP END PARALLEL DO
    status = DftiFreeDescriptor (FFT)
end

```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

2D Out-of-place Cluster FFT Computation

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len[2],v,i,j,n,s;
Complex *in,*out;

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,2,len);
// Ask necessary length of in and out arrays and allocate memory
DftiGetValueDM(desc,CDFLT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFLT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFLT_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
    for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();
```

1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len,v,i,n_out,s_out;
Complex *in,*work;

MPI_Init(...);
// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,1,len);
// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc,CDFLT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
work=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc,CDFLT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFLT_LOCAL_X_START,&s);
// Set work array as a workspace
DftiSetValueDM(desc,CDFLT_WORKSPACE,work);
// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0;i<n;i++) in[i]=f(i+s);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in);
```

```

DftiGetValueDM(desc,CDFT_LOCAL_OUT_NX,&n_out);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_X_START,&s_out);
// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]==g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();

```

Auxiliary Data Transformations

This section presents code examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Conversion from Cartesian to polar representation of complex data

```

// Cartesian->polar conversion of complex data
// Cartesian representation: z = re + I*im
// Polar representation: z = r * exp( I*phi )
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
                         double *r,double *phi)
{
    vdHypot(n,re,im,r);           // compute radii r[]
    vdAtan2(n,im,re,phi);        // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                         double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);               // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_im,temp_re,phi); // compute phases phi[]
}

```

Conversion from polar to Cartesian representation of complex data

```

// Polar->Cartesian conversion of complex data.
// Polar representation: z = r * exp( I*phi )
// Cartesian representation: z = re + I*im
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n,const double *r,const double *phi,
                         double *re,double *im)
{
    vdSinCos(n,phi,im,re);       // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,re,re);           // scale real part
    vdMul(n,r,im,im);           // scale imaginary part
}

void
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
                         MKL_Complex16 *z,
                         double *temp_re,double *temp_im)
{
    vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,temp_im,temp_im); // scale imaginary part
    vdMul(n,r,temp_re,temp_re); // scale real part
}

```

```
    vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re  
    vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im  
}
```

Specific Features of Fortran 95 Interfaces for LAPACK Routines

Intel® MKL implements Fortran 95 interface for LAPACK package, further referred to as MKL LAPACK95, to provide full capacity of MKL FORTRAN 77 LAPACK routines. This is the principal difference of Intel MKL from the Netlib Fortran 95 implementation for LAPACK.

A new feature of MKL LAPACK95 by comparison with Intel MKL LAPACK77 implementation is presenting a package of source interfaces along with wrappers that make the implementation compiler-independent. As a result, the MKL LAPACK package can be used in all programming environments intended for Fortran 95.

Depending on the degree and type of difference from Netlib implementation, the MKL LAPACK95 interfaces fall into several groups that require different transformations (see "[MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation](#)"). The groups are given in full with the calling sequences of the routines and appropriate differences from Netlib analogs.

The following conventions are used:

```
<interface> ::= <name of interface> '(' <arguments list> ')'
<arguments list> ::= <first argument> {<argument>}*
<first argument> ::= <identifier>
<argument> ::= <required argument>|<optional argument>
<required argument> ::= ',' <identifier>
<optional argument> ::= '[' ,<identifier> ']'
<name of interface> ::= <identifier>
```

where defined notions are separated from definitions by `::=`, notion names are marked by angle brackets, terminals are given in quotes, and `{...}* denotes repetition zero, one, or more times.`

`<first argument> and each <required argument>` should be present in all calls of denoted interface, `<optional argument>` may be omitted. Comments to interface definitions are provided where necessary. Comment lines begin with character `!`.

Two interfaces with one name are presented when two variants of subroutine calls (separated by types of arguments) exist.

Interfaces Identical to Netlib

FFTW Interface to Intel® Math Kernel Library

Intel® Math Kernel Library (Intel® MKL) offers FFTW2 and FFTW3 interfaces to Intel MKL Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW (www.fftw.org) to gain performance with Intel MKL without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel MKL. For ease of use, FFTW3 interface is also integrated in Intel MKL.

Notational Conventions

This appendix typically employs path notations for Windows* OS.

FFTW2 Interface to Intel® Math Kernel Library

This section describes a collection of wrappers providing FFTW 2.x interface to Intel MKL. The wrappers translate calls to FFTW 2.x functions into the calls of the Intel MKL Fast Fourier Transform interface (FFT interface).

The wrappers correspond to the FFTW version 2.x and the Intel MKL versions 7.0 or higher.

Because of differences between FFTW and Intel MKL FFT functionalities, there are restrictions on using wrappers instead of the FFTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to [chapter 11 "Fourier Transform Functions"](#), for better understanding the effects from the use of the wrappers.

More wrappers may be added in the future to extend FFTW functionality available with Intel MKL.

Wrappers Reference

The section provides a brief reference for the FFTW 2.x C interface. For details please refer to the original FFTW 2.x documentation available at www.fftw.org.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed in this section, are empty and do nothing, but they are provided to avoid link errors and satisfy the function calls.

Intel MKL FFT interface operates on both float and double-precision data types.

One-dimensional Complex-to-complex FFTs

The following functions compute a one-dimensional complex-to-complex Fast Fourier transform.

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);
fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

Multi-dimensional Complex-to-complex FFTs

The following functions compute a multi-dimensional complex-to-complex Fast Fourier transform.

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int flags,
                                         fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
                                         fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int flags,
                                         fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
            fftw_complex *out, int ostride, int odist);
void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);
void fftwnd_destroy_plan(fftwnd_plan plan);
```

One-dimensional Real-to-half-complex/Half-complex-to-real FFTs

Half-complex representation of a conjugate-even symmetric vector of size N in a real array of the same size N consists of $N/2+1$ real parts of the elements of the vector followed by non-zero imaginary parts in the reverse order. Because the Intel MKL FFT interface does not currently support this representation, all wrappers of this kind are empty and do nothing.

Nevertheless, you can perform one-dimensional real-to-complex and complex-to-real transforms using rfftwnd functions with $rank=1$.

Multi-dimensional Real-to-complex/Complex-to-real FFTs

The following functions compute multi-dimensional real-to-complex and complex-to-real Fast Fourier transforms.

```
rfftwnd_plan rfftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
rfftwnd_plan rfftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
rfftwnd_plan rfftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);

rfftwnd_plan rfftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir,
                                           int flags, fftw_real *in, int istride, fftw_real *out, int ostride);
rfftwnd_plan rfftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
                                           fftw_real *in, int istride, fftw_real *out, int ostride);
rfftwnd_plan rfftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir,
                                           int flags, fftw_real *in, int istride, fftw_real *out, int ostride);

void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in, int istride, int idist,
                             fftw_complex *out, int ostride, int odist);
void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
                             fftw_real *out, int ostride, int odist);
void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in, fftw_complex *out);
```

```
void rfftwnd_one_complex_to_real(rfftwnd_plan plan, fftw_complex *in, fftw_real *out);
void rfftwnd_destroy_plan(rfftwnd_plan plan);
```

Multi-threaded FFTW

This section discusses multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel MKL for the Linux* and Windows* operating systems, are described in [section "MPI FFTW Wrappers"](#).

Unlike the original FFTW interface, every computational function in the FFTW2 interface to Intel MKL provides multithreaded computation by default, with the number of threads defined by the number of processors available on the system (see section "Managing Performance and Memory" in the Intel MKL User's Guide). To limit the number of threads that use the FFTW interface, call the threaded FFTW computational functions:

```
void fftw_threads(int nthreads, fftw_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);
void fftw_threads_one(int nthreads, rfftwnd_plan plan, fftw_complex *in, fftw_complex
*out);
...
void rfftwnd_threads_real_to_complex( int nthreads, rfftwnd_plan plan, int howmany,
fftw_real *in, int istride, int idist, fftw_complex *out, int ostride, int odist);
```

Compared to its non-threaded counterpart, every threaded computational function has `threads_` as the second part of its name and additional first parameter `nthreads`. Set the `nthreads` parameter to the thread limit to ensure that the computation requires at most that number of threads.

FFTW Support Functions

The FFTW wrappers provide memory allocation functions to be used with FFTW:

```
void* fftw_malloc(size_t n);
void fftw_free(void* x);
```

The `fftw_malloc` wrapper aligns the memory on a 16-byte boundary.

If `fftw_malloc` fails to allocate memory, it aborts the application. To override this behavior, set a global variable `fftw_malloc_hook` and optionally the complementary variable `fftw_free_hook`:

```
void (*fftw_malloc_hook) (size_t n);
void (*fftw_free_hook) (void *p);
```

The wrappers use the function `fftw_die` to abort the application in cases when a caller cannot be informed of an error otherwise (for example, in computational functions that return `void`). To override this behavior, set a global variable `fftw_die_hook`:

```
void (*fftw_die_hook) (const char *error_string);
void fftw_die(const char *s);
```

Limitations of the FFTW2 Interface to Intel MKL

The FFTW2 wrappers implement the functionality of only those FFTW functions that Intel MKL can reasonably support. Other functions are provided as no-operation functions, whose only purpose is to satisfy link-time symbol resolution. Specifically, no-operation functions include:

- Real-to-half-complex and respective backward transforms
- Print plan functions
- Functions for importing/exporting/forgetting wisdom
- Most of the FFTW functions not covered by the original FFTW2 documentation

Because the Intel MKL implementation of FFTW2 wrappers does not use plan and plan node structures declared in `fftw.h`, the behavior of an application that relies on the internals of the plan structures defined in that header file is undefined.

FFTW2 wrappers define plan as a set of attributes, such as strides, used to commit the Intel MKL FFT descriptor structure. If an FFTW2 computational function is called with attributes different from those recorded in the plan, the function attempts to adjust the attributes of the plan and recommit the descriptor. Thus, repeated calls of a computational function with the same plan but different strides, distances, and other parameters may be performance inefficient.

Plan creation functions disregard most planner flags passed through the *flags* parameter. These functions take into account only the following values of *flags*:

- FFTW_IN_PLACE

If this value of *flags* is supplied, the plan is marked so that computational functions using that plan ignore the parameters related to output (*out*, *ostride*, and *odist*). Unlike the original FFTW interface, the wrappers never use the *out* parameter as a scratch space for in-place transforms.

- FFTW_THREADS

If this value of *flags* is supplied, the plan is marked read-only. An attempt to change attributes of a read-only plan aborts the application.

FFTW wrappers are generally not thread safe. Therefore, do not use the same plan in parallel user threads simultaneously.

Calling Wrappers from Fortran

The FFTW2 wrappers to Intel MKL provide the following subroutines for calling from Fortran:

```
call fftw_f77_create_plan(plan, n, dir, flags)
call fftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftw_f77_one(plan, in, out)
call fftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call fftw_f77_threads_one(nthreads, plan, in, out)
call fftw_f77_destroy_plan(plan)

call fftwnd_f77_create_plan(plan, rank, n, dir, flags)
call fftw2d_f77_create_plan(plan, nx, ny, dir, flags)
call fftw3d_f77_create_plan(plan, nx, ny, nz, dir, flags)
call fftwnd_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftwnd_f77_one(plan, in, out)
call fftwnd_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call fftwnd_f77_threads_one(nthreads, plan, in, out)
call fftwnd_f77_destroy_plan(plan)

call rfftw_f77_create_plan(plan, n, dir, flags)
call rfftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call rfftw_f77_one(plan, in, out)
call rfftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call rfftw_f77_threads_one(nthreads, plan, in, out)
call rfftw_f77_destroy_plan(plan)

call rfftwnd_f77_create_plan(plan, rank, n, dir, flags)
```

```

call rfftw2d_f77_create_plan(plan, nx, ny, dir, flags)
call rfftw3d_f77_create_plan(plan, nx, ny, nz, dir, flags)
call rfftwnd_f77_complex_to_real(plan, howmany, in, istride, idist, out, ostride,
odist)
call rfftwnd_f77_one_complex_to_real (plan, in, out)
call rfftwnd_f77_real_to_complex(plan, howmany, in, istride, idist, out, ostride,
odist)
call rfftwnd_f77_one_real_to_complex (plan, in, out)
call rfftwnd_f77_threads_complex_to_real(nthreads, plan, howmany, in, istride, idist,
out, ostride, odist)
call rfftwnd_f77_threads_one_complex_to_real(nthreads, plan, in, out)
call rfftwnd_f77_threads_real_to_complex(nthreads, plan, howmany, in, istride, idist,
out, ostride, odist)
call rfftwnd_f77_threads_one_real_to_complex(nthreads, plan, in, out)
call rfftwnd_f77_destroy_plan(plan)

call fftw_f77_threads_init(info)

```

The FFTW Fortran functions are actually the wrappers to FFTW C functions. So, their functionality and limitations are the same as of the corresponding C wrappers.

[Wrappers Reference](#)

[Limitations of the FFTW2 Interface to Intel MKL](#)

Installation

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers and makefiles with the wrapper list files are located in the .\interfaces\fftw2xc and .\interfaces\fftw2xf subdirectory in the Intel MKL directory for C and Fortran wrappers, respectively.

Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the .\interfaces\fftw2xc\wrappers subdirectory in the Intel MKL directory.

Three header files are used to compile the Fortran wrapper library: `fftw2_mkl.h`, `fftw2_f77_mkl.h`, and `fftw.h`. The `fftw2_mkl.h` and `fftw2_f77_mkl.h` files are located in the .\interfaces\fftw2xf\wrappers subdirectory in the Intel MKL directory.

The file `fftw.h`, used to compile libraries for both interfaces and located in the .\include\fftw subdirectory in the Intel MKL directory, slightly differs from the original FFTW (www.fftw.org) header file `fftw.h`.

The source code for the wrappers, makefiles, and function list files are located in subdirectories .\interfaces\fftw2xc and .\interfaces\fftw2xf in the Intel MKL directory for C and Fortran wrappers, respectively.

A wrapper library contains C or Fortran wrappers for complex and real transforms in a serial and multi-threaded mode for one of the two data types (`double` or `float`). A makefile parameter manages the data type.

The makefile parameters specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

Because a C compiler builds the Fortran wrapper library, function names in the wrapper library and Fortran object module may be different. The file `fftw2_f77_mkl.h` in the `.\interfaces\fftw2xf\source` subdirectory in the Intel MKL directory defines function names according to the names in the Fortran module. If a required name is missing in the file, you can modify the file to add the name before building the library.

To build the library, run the `make` command on Linux* OS and Mac OS* X or the `nmake` command on Windows* OS with appropriate parameters.

For example, the command

```
make libintel64
```

builds on Linux OS a double-precision wrapper library for Intel® 64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler version 9.1 or higher (compilers and data precision are chosen by default.).

Each makefile creates the library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/ia32` (on Linux OS and Mac OS X) or `.\lib\ia32` (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used compiler, the letter "f" precedes the underscore for Fortran, and the letter "c" precedes the underscore for C.

For example,

`fftw2xf_intel.lib` (on Windows OS); `libfftw2xf_intel.a` (on Linux OS and Mac OS X);

`fftw2xc_intel.lib` (on Windows OS); `libfftw2xc_intel.a` (on Linux OS and Mac OS X);

`fftw2xc_ms.lib` (on Windows OS); `libfftw2xc_gnu.a` (on Linux OS and Mac OS X).

Application Assembling

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

Intel MKL provides examples to demonstrate how to use the MPI FFTW wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw2xc` and `.\examples\fftw2xf` subdirectories in the Intel MKL directory for C and Fortran, respectively. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, `rfftw_threads.h`, and `fftw_f77.i`. These files are distributed with permission from FFTW and are available in `.\include\fftw`. The original files can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

An example makefile uses the `function` parameter in addition to the parameters that the respective wrapper library makefile uses (see [Creating a Wrapper Library](#)). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes examples. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to examples.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `._results` is created, and the results are stored there in the `<example_name>.res` files.

MPI FFTW Wrappers

MPI FFTW wrappers for FFTW 2 are available only with Intel® MKL for the Linux* and Windows* operating systems.

MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

Complex MPI FFTW

Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir, int flags);
void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work);
void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start, int *local_n_after_transform, int *local_start_after_transform, int *total_local_size);
void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE, FFTW_MEASURE, FFTW_SCRAMBLED_INPUT and FFTW_SCRAMBLED_OUTPUT. The same algorithm corresponds to all these values of the *flags* parameter. If any other *flags* value is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown *flags*'.
- The only supported value of *n_fields* is 1.

Complex Multi-dimensional MPI FFTW Transforms

```
fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);
fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction dir, int flags);
void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work, fftwnd_mpi_output_order output_order);
void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int *local_x_start, int *local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);
void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown *flags*'.
- The only supported value of *n_fields* is 1.

Real MPI FFTW

Real-to-Complex MPI FFTW Transforms

```
rfftwnd_mpi_plan rfftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);
rfftwnd_mpi_plan rfftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);
rfftwnd_mpi_plan rfftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction dir, int flags);
void rfftwnd_mpi(rfftwnd_mpi_plan p, int n_fields, fftw_real *local_data, fftw_real *work, fftwnd_mpi_output_order output_order);
```

```
void rfftwnd_mpi_local_sizes(rfftwnd_mpi_plan p, int *local_nx, int *local_x_start, int
*local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);
void rfftwnd_mpi_destroy_plan(rfftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n_fields* is 1.

- Function *rfftwnd_mpi_create_plan* can be used for both one-dimensional and multi-dimensional transforms.
 - Both values of the *output_order* parameter are supported: FFTW_NORMAL_ORDER and FFTW_TRANSPOSED_ORDER.
-

Creating MPI FFTW Wrapper Library

The source code for the wrappers, makefile, and wrapper list file are located in the .\interfaces\fftw2x_cdft subdirectory in the Intel MKL directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see [MPI FFTW Wrappers Reference](#).

The makefile parameters specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux* OS and Mac OS* X or the `nmake` command on Windows* OS with appropriate parameters.

For example, the command

```
make libintel64
```

builds on Linux OS a double-precision wrapper library for Intel® 64 architecture based applications using Intel MPI 2.0 and the Intel® C++ Compiler version 9.1 or higher (compilers and data precision are chosen by default.).

The makefile creates the wrapper library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/ia32` (on Linux OS) or `.\lib\ia32` (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

`fftw2x_cdft_SINGLE.lib` on Windows OS;

`libfftw2x_cdft_DOUBLE.a` on Linux OS.

Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW2. The source C code for the examples, makefiles used to run them, and the example list files are located in the .\examples\fftw2x_cdft subdirectory in the Intel MKL directory. To build examples, one additional file `fftw_mpi.h` is needed. This file is distributed with permission from FFTW and is available in .\include\fftw. The original file can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefile comment headings and are similar to the wrapper library makefile parameters (see [Creating MPI FFTW Wrapper Library](#)).

The table below lists examples available in the .\examples\fftw2x_cdft\source subdirectory.

Examples of MPI FFTW Wrappers

Source file for the example	Description
wrappers_c1d.c	One-dimensional Complex MPI FFTW transform, using <code>plan = fftw_mpi_create_plan(...)</code>
wrappers_c2d.c	Two-dimensional Complex MPI FFTW transform, using <code>plan = fftw2d_mpi_create_plan(...)</code>
wrappers_c3d.c	Three-dimensional Complex MPI FFTW transform, using <code>plan = fftw3d_mpi_create_plan(...)</code>
wrappers_c4d.c	Four-dimensional Complex MPI FFTW transform, using <code>plan = fftwnd_mpi_create_plan(...)</code>
wrappers_r1d.c	One-dimensional Real MPI FFTW transform, using <code>plan = rfftw_mpi_create_plan(...)</code>
wrappers_r2d.c	Two-dimensional Real MPI FFTW transform, using <code>plan = rfftw2d_mpi_create_plan(...)</code>
wrappers_r3d.c	Three-dimensional Real MPI FFTW transform, using <code>plan = rfftw3d_mpi_create_plan(...)</code>
wrappers_r4d.c	Four-dimensional Real MPI FFTW transform, using <code>plan = rfftwnd_mpi_create_plan(...)</code>

FFTW3 Interface to Intel® Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel MKL. The wrappers translate calls of FFTW3 functions to the calls of the Intel MKL Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel MKL Fourier transforms without changing the program source code.

The wrappers correspond to the FFTW release 3.2 and the Intel MKL releases starting with 10.2. **For a detailed description of FFTW interface, refer to www.fftw.org.** For a detailed description of Intel MKL FFT and TT functionality the wrappers use, see [chapter 11](#) and [section "Trigonometric Transform Routines" in chapter 13](#), respectively.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.2 library, because of differences between FFTW and Intel MKL FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel MKL. More functionality may be added to the wrappers and Intel MKL in the future to reduce the constraints of the FFTW3 interface to Intel MKL.

The FFTW3 wrappers are integrated in Intel MKL. The only change required to use Intel MKL through the FFTW3 wrappers is to link your application using FFTW3 against Intel MKL.

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel MKL distribution. You can use the reference implementation to create your own wrapper library (see [Building Your Own Wrapper Library](#))

Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This manual does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments particular limitations of the wrappers and provides usage hints:

- The FFTW3 wrappers do not support long double precision because Intel MKL FFT functions operate only on single- and double-precision floating-point data types (`float` and `double`, respectively). Therefore the functions with prefix `fftwl_`, supporting the `long double` data type, are not provided.
- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in header files `fftw3.h` and `fftw3.f`. These files are borrowed from the FFTW3.2 package and distributed within Intel MKL with permission. Additionally, files `fftw3_mkl.h`, `fftw3_mkl.f`, and `fftw3_mkl_f77.h` define supporting structures, supplementary constants and macros, and expose Fortran interface in C.
- Actual functionality of the plan creation wrappers is implemented in guru64 set of functions. Basic interface, advanced interface, and guru interface plan creation functions call the guru64 interface functions. Thus, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
 - c2r and r2c problems with a split storage of complex data.
 - r2r problems with *kind* values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported r2r kinds are even/odd DFTs (sine/cosine transforms).
 - Multidimensional r2r transforms.
 - Transforms of multidimensional vectors. That is, the only supported values for parameter `howmany_rank` in guru and guru64 plan creation functions are 0 and 1.
 - Multidimensional transforms with `rank > MKL_MAXRANK`.
- The `MKL_RODFT00` value of the *kind* parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this *kind* value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

Both plans perform the same transform, except that the `in2/out2` arrays have one extra zero element at location 0. For example, if `n=3`, `in1={x,y,z}` and `out1={u,v,w}`, then `in2={0,x,y,z}` and `out2={0,u,v,w}`.

- The *flags* parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, *flags* values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- FFTW3 wrappers are not fully thread safe. If the new-array execute functions, such as `fftw_execute_dft()`, share the same plan from parallel user threads, set the number of the sharing threads before creation of the plan. For this purpose, the FFTW3 wrappers provide a header file `fftw3_mkl.h`, which defines a global structure `fftw3_mkl` with a field to be set to the number of sharing threads. Below is an example of setting the number of sharing threads:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.number_of_user_threads = 4;
plan = fftw_plan_dft(...);
```

- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.
- The FFTW3 wrappers to Intel MKL use the 32-bit `int` type in both LP64 and ILP64 interfaces of Intel MKL. Use guru64 FFTW3 interfaces for 64-bit sizes.
- Fortran wrappers (see [Calling Wrappers from Fortran](#)) use the `INTEGER` type, which is 32-bit in LP64 interfaces and 64-bit in ILP64 interfaces.

- The wrappers typically indicate a problem by returning a `NULL` plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable `fftw3_mkl.verbose` to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
 - For saving, loading, and printing plans
 - For saving and loading wisdom
 - For estimating arithmetic cost of the transforms.
- Do not use macro `FFTW_DLL` with the FFTW3 wrappers to Intel MKL.
- Do not use negative stride values. Though FFTW3 wrappers support negative strides in the part of advanced and guru FFTW interface, the underlying implementation does not.

Calling Wrappers from Fortran

Intel MKL also provides Fortran 77 interfaces of the FFTW3 wrappers. The Fortran wrappers are available for all FFTW3 interface functions and are based on C interface of the FFTW3 wrappers. Therefore they have the same functionality and restrictions as the corresponding C interface wrappers.

The Fortran wrappers use the default `INTEGER` type for integer arguments. The default `INTEGER` is 32-bit in Intel MKL LP64 interfaces and 64-bit in ILP64 interfaces. Argument `plan` in a Fortran application must have type `INTEGER*8`.

The wrappers that are double-precision subroutines have prefix `dfftw_`, single-precision subroutines have prefix `sfftw_` and provide an equivalent functionality. Long double subroutines (with prefix `lfftw_`) are not provided.

The Fortran FFTW3 wrappers use the default Intel® Fortran compiler convention for name decoration. If your compiler uses a different convention, or if you are using compiler options affecting the name decoration (such as `/Qlowercase`), you may need to compile the wrappers from sources, as described in section [Building Your Own Wrapper Library](#).

For interoperability with C, the declaration of the Fortran FFTW3 interface is provided in header file `include/fftw/fftw3_mkl_f77.h`.

You can call Fortran wrappers from a FORTRAN 77 or Fortran 90 application, although Intel MKL does not provide a Fortran 90 module for the wrappers. For a detailed description of the FFTW Fortran interface, refer to FFTW3 documentation (www.fftw.org).

The following example illustrates calling the FFTW3 wrappers from Fortran:

```
INTEGER*8 plan
INTEGER N
INCLUDE 'fftw3.f'
COMPLEX*16 IN(*), OUT(*)
!...initialize array IN
CALL DFFTWR PLAN DFT_1D(PLAN, N, IN, OUT, -1, FFTW_ESTIMATE)
IF (PLAN .EQ. 0) STOP
CALL DFFTWR EXECUTE
!...result is in array OUT
```

Building Your Own Wrapper Library

The FFTW3 wrappers to Intel MKL are delivered both integrated in Intel MKL and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself. However, if your Fortran application is compiled with a compiler that uses a different name decoration than the Intel® Fortran compiler or if you are using compiler options altering the Fortran name decoration, you may need to build the wrappers that use the appropriate name changing convention.

The source code for the wrappers, makefiles, and function list files are located in subdirectories .\interfaces\fftw3xc and .\interfaces\fftw3xf in the Intel MKL directory for C and Fortran wrappers, respectively.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS and Mac OS* X or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target, that is, one of {libia32, libintel64}, defines the platform architecture, and the other parameters facilitate selection of the compiler, size of the default INTEGER type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the `makefile`.

In the following example, the `make` command is used to build the FFTW3 Fortran wrappers to MKL for use from the GNU g77 Fortran compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xf
make libintel64 compiler=gnu fname=a_name__ install_to=/my/path
```

This command builds the wrapper library using the GNU gcc compiler, decorates the name with the second underscore, and places the result, named `libfftw3xf_gcc.a`, into directory `/my/path`. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter.

Building an Application

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel MKL at the link stage (see section "*Linking Your Application with Intel® Math Kernel Library*" in the *Intel MKL User's Guide*).

If you recompile your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires

```
#include "fftw3.h",
which it probably already includes.
```

- The application does not require

```
#include "mkl_dfti.h" .
```

- The application does not require

```
#include "fftw3_mkl.h" .
```

It is required only in case you want to use the `MKL_RODFT00` constant.

- If the application does not check whether a `NULL` plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel MKL wrappers do not provide 100% of FFTW3 functionality.
- If the application is threaded, take care about shared plans, because the execute functions in the wrappers are not thread safe, unlike the original FFTW3 functions. See a [note about setting `fftw3_mkl.number_of_user_threads`](#) in section "[Using FFTW3 wrappers](#)".

Running Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the .\examples\fftw3xc and .\examples\fftw3xf subdirectories in the Intel MKL directory. To build Fortran examples, one additional file `fftw3.f` is needed. This file is distributed with permission from FFTW and is available in the .\include\fftw subdirectory of the Intel MKL directory. The original file can also be found in FFTW 3.2 at <http://www.fftw.org/download.html>.

Example makefile parameters are similar to the wrapper library makefile parameters. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory `._results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

MPI FFTW Wrappers

This section describes a collection of MPI FFTW wrappers to Intel® MKL. The wrappers correspond to the FFTW 3.3 Alpha release and the Intel MKL releases starting with 10.3. For a detailed description of the MPI FFTW interface, refer to www.fftw.org.

MPI FFTW wrappers are available only with Intel MKL for the Linux* and Windows* operating systems.

These wrappers translate calls of MPI FFTW functions to the calls of the Intel MKL cluster Fourier transform (CFFT) functions. The purpose of the wrappers is to enable users of MPI FFTW functions improve performance of the applications without changing the program source code.

Although the MPI FFTW wrappers provide less functionality than the original FFTW 3.3 because of differences between MPI FFTW and Intel MKL CFFT, the wrappers cover many typical CFFT use cases.

The MPI FFTW wrappers are provided as source code. To use the wrappers, you need to build your own wrapper library (see [Building Your Own Wrapper Library](#)).

[Cluster FFT Functions](#)

Building Your Own Wrapper Library

The MPI FFTW wrappers for FFTW3 are delivered as source code, which can be compiled to build a wrapper library.

The source code for the wrappers, makefiles, and function list files are located in subdirectory `.\interfaces\fftw3x_cdft` in the Intel MKL directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target, that is, one of `{libia32, libintel64}`, defines the platform architecture, and the other parameters specify the compiler, size of the default INTEGER type, as well as the name and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the MPI FFTW wrappers to Intel MKL for use from the GNU C compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3x_cdft
make libintel64 compiler=gnu mpi=openmpi INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler so that the final user executable can use Open MPI and places the result, named `libfftw3x_cdft_DOUBLE.a`, into directory `/my/path`.

Building an Application

Normally, the only change needed to build your application with MPI FFTW wrappers replacing original FFTW3 library is to add Intel MKL and the wrapper library at the link stage (see section "[Linking Your Application with Intel® Math Kernel Library](#)" in the [Intel MKL User's Guide](#)).

When you are recompiling your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW3. The source code for the examples, makefiles used to run them, and the example list files are located in the .\examples\fftw3x_cdft subdirectory in the Intel MKL directory.

Example makefile parameters are similar to the wrapper library makefile parameters. Example makefiles normally build and invoke the examples. Results of running the examples are saved in subdirectory ._results in files with extension .res.

For detailed information about options for the example makefile, refer to the makefile.

Glossary

A^H	Denotes the conjugate transpose of a general matrix A . See also conjugate matrix.
A^T	Denotes the transpose of a general matrix A . See also transpose.
band matrix	A general m -by- n matrix A such that $a_{ij} = 0$ for $ i - j > l$, where $1 < l < \min(m, n)$. For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.
BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix A in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$) where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .
c	When found as the first letter of routine names, c indicates the usage of single-precision complex data type.
CBLAS	C interface to the BLAS. See BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable x . For univariate distribution the cumulative distribution function is the function of real argument x , which for every x takes a value equal to probability of the event A : $x \leq x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$, which, for every x , takes a value equal to probability of the event $A = (x_1 \leq x_1 \& x_2 \leq x_2 \& \dots \& x_n \leq x_n)$.
Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A in the form $A = U^H U$ or $A = LL^H$, where L is a lower triangular matrix and U is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix A as follows: $\kappa(A) = A \cdot A^{-1} .$

conjugate matrix	The matrix A^H defined for a given general matrix A as follows: $(A^H)_{ij} = (a_{ji})^*$.
conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$.
d	When found as the first letter of routine names, d indicates the usage of double-precision real data type.
dot product	The number denoted $x \cdot y$ and defined for given vectors x and y as follows: $x \cdot y = \sum_i x_i y_i$. Here x_i and y_i stand for the i -th elements of x and y , respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $2.23 \times 10^{-308} < x < 1.79 \times 10^{308}$. For this data type, the machine precision ϵ is approximately 10^{-15} , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
eigenvalue	See eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors x and numbers λ (for a given square matrix A) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix A and the vectors x are called the eigenvectors of the matrix A .
eigenvector	See eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where v is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix Q in the QR factorization (the matrix Q is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, LU factorization, LQ factorization, QR factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.
full storage	A storage scheme allowing you to store matrices of any kind. A matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
Hermitian matrix	A square matrix A that is equal to its conjugate matrix A^H . The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	See identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix A , $AI = A$ and $IA = A$.
i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel MKL	Abbreviation for Intel® Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix A as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices A .
LQ factorization	Representation of an m -by- n matrix A as $A = LQ$ or $A = (L \ 0)Q$. Here Q is an n -by- n orthogonal (unitary) matrix. For $m \leq n$, L is an m -by- m lower triangular matrix with real diagonal elements; for $m > n$,

<i>LU</i> factorization	where L_1 is an n -by- n lower triangular matrix, and L_2 is a rectangular matrix.
	Representation of a general m -by- n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).
machine precision	The number ϵ determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. See also double precision and single precision.
MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.
orthogonal matrix	A real square matrix A whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.
packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable x . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$. For univariate distribution the relation is
	$F(x) = \int_{-\infty}^x f(t)dt .$
	For multivariate distribution the relation is
	$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n$
positive-definite matrix	A square matrix A such that $\mathbf{Ax} \cdot \mathbf{x} > 0$ for any non-zero vector \mathbf{x} . Here \cdot denotes the dot product.
pseudorandom number generator	A completely deterministic algorithm that imitates truly random sequences.
<i>QR</i> factorization	Representation of an m -by- n matrix A as $A = QR$, where Q is an m -by- m orthogonal (unitary) matrix, and R is n -by- n upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if $m < n$) matrix.
random stream	An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.

RNG	Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.
Rectangular Full Packed (RFP) storage	A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.
s	When found as the first letter of routine names, s indicates the usage of single-precision real data type.
ScalAPACK	Stands for Scalable Linear Algebra PACKage.
Schur factorization	Representation of a square matrix A in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex A , triangular matrix) called the Schur form of A ; the matrix Z is orthogonal (for complex A , unitary). Columns of Z are called Schur vectors.
single precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $1.18 \times 10^{-38} < x < 3.40 \times 10^{38}$. For this data type, the machine precision (ϵ) is approximately 10^{-7} , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
singular matrix	A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $AX = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H . See also SVD.
SMP	Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. See BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. See full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. See also Singular value decomposition section in Chapter 5.
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.
transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T , and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1 A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.
triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^HA = I$. All eigenvalues of a unitary matrix have the absolute value 1.

VML	Abbreviation for Vector Mathematical Library. See Chapter 9 of this book.
VSL	Abbreviation for Vector Statistical Library. See Chapter 10 of this book.
<i>z</i>	When found as the first letter of routine names, <i>z</i> indicates the usage of double-precision complex data type.
